Abstract

We derive group branching laws for formal characters of subgroups $H_\pi$ of $GL(n)$ leaving invariant an arbitrary tensor $T^\pi$ of Young symmetry type $\pi$ where $\pi$ is an integer partition. The branchings $GL(n) \downarrow GL(n-1)$, $GL(n) \downarrow O(n)$ and $GL(2n) \downarrow Sp(2n)$ fixing a vector $v$, a symmetric tensor $g_{ij} = g_{ji}$, and an antisymmetric tensor $f_{ij} = -f_{ji}$, respectively, are obtained as special cases. All new branchings are governed by Schur function series obtained from plethysms of the Schur function $s_{\pi} \equiv \{\pi\}$ by the basic $M$ series of complete symmetric functions and the $L = M^{-1}$ series of elementary symmetric functions. Our main technical tool is that of Hopf algebras, and our main result is the derivation of a coproduct for any Schur function series obtained by plethysm from another such series. Therefrom one easily obtains $\pi$-generalized Newell-Littlewood formulae, and the algebra of the formal group characters of these subgroups is established. Concrete examples and extensive tabulations are displayed for $H_{13}$, $H_{21}$, and $H_3$, showing their involved and nontrivial representation theory. The nature of the subgroups is shown to be in general affine, and in some instances non reductive. We discuss the complexity of the coproduct formula and give a graphical notation to cope with it. We also discuss the way in which the group branching laws can be reinterpreted as twisted structures deformed by highly nontrivial 2-cocycles. The algebra of subgroup characters is identified as a cliffordization of the algebra of symmetric functions for $GL(n)$ formal characters. Modification rules are beyond the scope of the present paper, but are briefly discussed.

Keywords: Group branchings, symmetric functions, plethysm, Hopf algebra, Schur function series, formal characters, Newell-Littlewood theorem, representation theory

1 Introduction

The use of explicit tensorial notation for handling the representation theory of the classical groups is a natural tool in many branches of mathematics and of mathematical or theoretical physics. The theory was formalized by Weyl [35], and the associated character techniques involving applications of symmetric functions developed especially by Littlewood [23]. For modern accounts of combinatorial representation theory, and its connections to other branches of mathematics, we refer to the review article of Barcelo and Ram [1] and for the theory of symmetric functions to the classic text of Macdonald [30]. A milestone in practical applications of these techniques is the survey paper [2] which gives systematic rules for handling partition notation for labeling (finite dimensional) representations of simple Lie groups, together with their branching rules to common subgroups, and for the resolution of their Kronecker products. An example of
applications of Kronecker products is provided by [13]. A necessary concomitant of these techniques is the automation provided by a symbolic computer package such as SCHUR \( \text{⃝} \) [36]. Finally, some of these techniques have been found to generalize to the representation theory of non-compact groups [19, 17, 18].

In a recent paper [10] the role of symmetric functions in relation to group representation theory has been re-considered from the viewpoint of the underlying Hopf algebraic structure. This structure is in fact well known in the combinatorial literature [34, 33, 31]. In [10] the formalism of branching rules was aligned with certain endomorphisms on the algebra of symmetric functions, called branching operators, derived from 1-cocycles, for which the multiplicative cohomology of Sweedler [32] provides a natural analytical setting and classification. Standard branchings from generic symmetric functions to symmetric functions of orthogonal or symplectic type (the classic Newell-Littlewood theorems for the group reduction from GL(\(n\)) \(\downarrow\) O(\(n\)) or GL(\(n\)) \(\downarrow\) Sp(\(n\))) were found to be derived from certain 2-cocycles (for which associativity is guaranteed).

This result then prompts the more general question of classifying arbitrary, non-cohomologous, 2-cocycles, and the nature of any associated character theory and of the algebraic or group structures which might be entrained therewith. While an ab initio approach to this question is extremely difficult at this level, there is an obvious strategy for finding such generalizations. Namely one should look for ‘branching rules’ which are a direct generalization of those due to Littlewood and for which there is a known underlying classical matrix group. Apart from exceptional groups associated with specific invariants in sporadic dimensions, cases arising from local isomorphisms, and also the GL(\(n\)) \(\downarrow\) SL(\(n\)) family (see section 3 below), such groups are necessarily not classical groups, as these are already exhausted by the orthogonal and symplectic series. Since one studies group characters associativity is guaranteed, and the associated 2-cochains are once again 2-cocycles.

This infinite reservoir of ‘new branching rules’ is revealed by simply looking for formal characters associated with matrix subgroups of GL(\(n\)) which fix a certain tensor \(T_\pi\) of arbitrary symmetry type, say corresponding to a partition \(\pi\). The corresponding branching rules from GL(\(n\)) to such subgroups thus form the topic of investigation in the present paper.

The plan of the paper is as follows. In the section 2 below we introduce the main propositions about coproducts of infinite Schur function series, quotients of products by such series, and products of formal characters of subgroups, all based on plethysms of the \(M\)-series. These results then form the basis of the calculation of ‘new branching rules’ from GL(\(n\)) to some matrix subgroups \(H_\pi\) that are exemplified in section 3, with both modification rules and product rules for \(H_1\) for dimension \(n = 3, 4\). Further tabulations are provided for the cases \(H_{21}\) and \(H_2\) in appendix C. All this is presented in the standard notation for symmetric functions, in a purely combinatorial way. Then we switch in section 4 to the much more handy and compact Hopf algebra language, giving a Hopf algebra proof of the same results. Thereafter we give only Hopf proofs in the main text, and collect the combinatorial proofs in appendix B. Technically the new branching rules are generated by skewing with certain infinite formal series of symmetric functions which are generalizations of those used by Littlewood, and some related ones needed for handling such cases as spinor and composite tensor representations. From the analysis we also derive the \(\pi\)-generalised Newell-Littlewood product formula (Proposition 2.7, Theorem 4.18).

An underlying theme of this work is the use of Littlewood’s operation of plethysm [27, 23] of symmetric functions which emerges as pivotal to the generation of the new branching rules. Plethysms are defined in section 2 below, and in all subsequent sections play a central role. Specifically, in section 4.2 key results concerning plethysms of Schur function series are derived (Main Theorems i) and ii), Theorems 4.12 and 4.13 respectively); in section 4.4 it is shown how plethysms allow one to construct an infinity of noncohomologous 2-cochains. A graphical calculus of tangle diagrams for interpreting this analysis is given in appendix A. A further study of plethysms from the viewpoint of the Hopf algebra structure of symmetric functions, as developed in [10], is in preparation [11].

**Dedication:**
This work is dedicated to the memory of our friend and colleague Brian G. Wybourne, who was born on 3rd May 1935 in Morrinsville, New Zealand and died on 26th November 2003 in Torun, Poland. It was Brian’s typically inquisitive response to a draft copy of the ‘Hopf laboratory for symmetric functions’ paper of BF and PDJ [10] that encouraged him together with RCK, in the autumn of 2003 while Brian was on one of his annual visits to Southampton, to look for examples of non-classical Lie groups with ‘new’ branching rules. That discussion led on to the present joint collaboration. We trust that our results, although only
an initial foray into a technically difficult area of combinatorial representation theory, are in keeping with Brian’s vision for some of the last research that occupied him before his untimely death.

2 Schur functions and Schur function series

2.1 Basic notions

As mentioned in the introduction, in this work we are dealing with formal group characters, which generically may be regarded as particular sorts of symmetric functions. Abstractly these lie in the ring of invariant polynomials \( \Lambda^n = \mathbb{Z}[x_1, x_2, \ldots, x_n]^{S_n} \) in indeterminates \( x_1, x_2, \ldots, x_n \), which are symmetric in their arguments. Via an inductive limit one passes over to infinitely many variables obtaining a graded ring \( \Lambda = \bigoplus \Lambda^n \). As is well known, there are many bases for symmetric functions whose products and sums suffice to build up arbitrary symmetric polynomials [30]. Of particular interest for this paper are the so-called Schur functions. With an appropriate interpretation of \( x = (x_1, x_2, \ldots, x_n) \), the Schur function \( s_\lambda(x) \), or \( \{ \lambda \} \) in the notation of Littlewood [23], is the character of the irreducible representation \( V^\lambda \) of \( GL(n) \) of highest weight \( \lambda \). In this notation \( \lambda \) is an integer partition, that is \( \lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell) \), an ordered \( \ell \)-tuple of positive integers such that \( \lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_\ell \); \( \lambda \) is a partition of \( \omega_\lambda \equiv |\lambda| := \sum \lambda_i \), and the number of parts or length of the partition is \( \ell(\lambda) \) or just \( \ell \) in this case.

The ring of symmetric functions \( \Lambda = \mathbb{Z}[x_1, x_2, \ldots] \) admits various operations, such as addition and (outer) multiplication. The latter gives rise in the Schur function basis to the famous Littlewood-Richardson coefficients as the structure constants in the product

\[
s_\lambda(x) \cdot s_\mu(x) = \sum_\nu C_{\lambda\mu}^\nu s_\nu(x).
\]

Reciprocally, there is an adjoint (outer) skew operation such that,

\[
s_{\nu/\mu}(x) = \sum_\lambda C_{\lambda\mu}^\nu s_\lambda(x).
\]

Additional symmetric function definitions will be introduced in the sequel as they arise. It should be noticed that we are flexible as to whether the discussion covers universal characters, where the number of indeterminates is formally infinite. Then the polynomial ring is being extended to the closure using the inductive limit of letting the number of variable tend to infinity. Doing that, one knows that so-called syzygies are avoided, and such formal representation modules are flat. By contrast for symmetric functions with a finite number \( n \) of variables, for example model subgroups of \( GL(n) \), one hits the problem of dealing with such syzygies. This amounts to introducing further relations, the so called modification rules. A systematic treatment of modification rules for non classical groups is beyond the scope of the paper, but we will exhibit a few instances to show how to cope with them in practice. Generally speaking our aim is to display a variety of examples for specific matrix groups, for which a finite number of variables is necessary and intended. However, one should keep in mind that abstract arguments, for example in section 4, are dealt with in the infinite variable case. This is common practice in the classical theory too.

2.2 Plethysm

One more advanced piece of symmetric function formalism, that of plethysm, is central to the structure of Schur function series and branching rules old and new. We give notation and some formal definitions here. We denote Schur functions as \( s_\lambda \), or \( \{ \lambda \} \) in Littlewood’s bracket notation.

2.2.1 Plethysm as composition

The mathematical definition of plethysm is given by the composition of Schur functions, \( s_\mu[s_\lambda] \). Using Littlewood’s notation for Schur functions \( s_\lambda \equiv \{ \lambda \} \), it is customary to write a plethysm using the symbol for a tensor product \( s_\nu[s_\lambda] \equiv \{ \lambda \} \otimes \{ \mu \} \) with reversed terms. We use the underlined tensor product symbol \( \otimes \) for plethysm, to make a distinction with the tensor sign \( \otimes \) appearing in the Hopf algebra development.
general formula
jectively embedded in the fundamental representation of the group
the character of an irreducible
function is given by
Example 2.1
Consider two groups
Example 2.1: Consider \( s_{(2)}[s_{(1,2)}](x_1, \ldots, x_4) \).
\( s_{(2)}[s_{(1,2)}](x_1, \ldots, x_4) = x_1x_2 + x_1x_3 + x_1x_4 + x_2x_3 + x_2x_4 + x_3x_4 \)
which leads to the expansion of the composition \( s_{(2)}[s_{(1,2)}] \) as
\( \lambda \) (shape)

2.2.2 Plethysms related to branchings
Consider two groups \( \text{GL}(m), \text{GL}(n) \), with \( m > n \). Consider a Schur function \( \{ \lambda \} \) which represents the character of an irreducible \( m \)-dimensional representation of \( \text{GL}(n) \). This representation can be subjectively embedded in the fundamental representation of the group \( \text{GL}(m) \) whose character is \( \{ 1 \} \). The branching process \( \text{GL}(m) \to \text{GL}(n) \) is then described by the injective map \( \{ 1 \} \to \{ \lambda \} \) which leads to the general formula
\[
\text{GL}(m) \to \text{GL}(n) : \quad \{ \mu \} \to \{ \lambda \} \otimes \{ \mu \} \tag{2.7}
\]
This process, intimately related to physics, is the origin of the usage of the tensor symbol \( \otimes \). The connection with the previous definition of a plethysm as a composition comes about because the \( \text{GL}(n) \) character \( \{ \lambda \} \) is nothing other than the Schur function \( s_{\lambda}(x) \), with a suitable identification of \( \lambda \). Its dimension \( m \), obtained by setting all \( x_i = 1 \), is just the number of monomials \( y_i \) in \( s_{\lambda}(x) \), and \( s_{\mu}(y) \) is the corresponding \( \text{GL}(m) \) character \( \{ \mu \} \).
In terms of modules, let \( V^\lambda \) be the \( \text{GL}(n) \)-module with character \( \{ \lambda \} \) and dimension \( m \). This module may be identified with the defining \( \text{GL}(m) \)-module \( V \) on which \( \text{GL}(m) \) acts naturally. Then the plethysm \( \{ \lambda \} \otimes \{ \mu \} \) arises as the character of the \( \text{GL}(m) \)-module \( V^\mu = (V^\lambda)^\mu \) viewed as a \( \text{GL}(n) \)-module. As a result of this interpretation it is sometimes convenient to adopt a notation for plethysms whereby the corresponding character is denoted not by \( \{ \lambda \} \otimes \{ \mu \} \), but by \( \{ \lambda \} \circ \{ \mu \} \).
2.2.3 Plethysms and outer exponentiation

Plethysm can be tied to the following problem of invariants of matrices \( |A^\lambda| \). For example the characteristic polynomial gives a relationship between the roots \( x_i \), that is invariants, and the coefficients of the polynomials. The process of evaluating a plethysm is the same as that of computing the coefficients of the characteristic polynomial having roots \( x_i^k \) from the coefficients of the original polynomial. In general one tries to compute the invariant \( |A^\lambda|^\mu \) where \( \mu \) is a partition of \( k \). The relation to outer product tensor powers is then as follows. The plethysm

\[
\{\lambda\} \otimes \{\mu\} = \sum_{\nu} p_{\lambda,\mu}^{\nu} \{\nu\},
\]

with non-negative integers \( p_{\lambda,\mu}^{\nu} \), appears in the outer tensor product \( k \)-fold power of the Schur function \( \{\lambda\} \) given by

\[
\{\lambda\}^k = \sum_{\mu,|\mu|=k} f^{\mu} \{\lambda\} \otimes \{\mu\},
\]

where the multiplicity \( f^{\mu} \) is the dimension of the irreducible representation \( \{\mu\} \) of the symmetric group \( S_k \). This makes it clear that the plethysm \( \{\lambda\} \otimes \{\mu\} \) is nothing other than the character of the \( \{\mu\} \)-symmetrised tensor power of the \( GL(n) \)-module \( V^\lambda \), justifying yet again the exponential notation \( \{\lambda\} \circledast \{\mu\} \) that we will meet in our main theorem. As iterated outer multiplication, that is exponentiation, the operation of plethysm is of course not commutative, and satisfies various forms of right and left distributivity, which in fact can be used to compute plethysms iteratively. Details are deferred to section 4.2 below, where the results are needed.

2.3 Schur function series

Littlewood [23] introduced a set of infinite Schur function series which, much later allowed King [15] to formulate various identities and branching rules in an extremely compact notation. These identities have been extended by King, Dehuai and Wybourne [16] and later by Yang and Wybourne [37]; we follow the presentation of the latter.

A Schur function series is an infinite series of Schur functions often given via a generating function defining a formal power series. The most basic Schur function series are the mutually inverse series \( L \) and \( M = L^{-1} \).

\[
L_t(x) = \prod_{i=1}^{\infty} (1 - x_i t) \quad M_t(x) = \prod_{i=1}^{\infty} (1 - x_i t)^{-1} = L_t^{-1}(x)
\]

from which the others may be derived using plethysm, sum and product. The Schur function content of these mutually inverse series is

\[
L_t(x) = \sum_{m=0}^{\infty} (-1)^m s_{\{1^m\}}(x) t^m = \sum_{m=0}^{\infty} (-1)^m \{1^m\} t^m, \quad M_t(x) = \sum_{m=0}^{\infty} s_{\{m\}}(x) t^m = \sum_{m=0}^{\infty} \{m\} t^m,
\]

again using the notation \( \{\lambda\} \) of Littlewood for a Schur function \( s_{\lambda}(x) \).

Furthermore it is convenient to follow Yang and Wybourne to introduce the conjugate (with respect to transposed partitions) series, signified by \( ^\dagger \), and the inverse conjugate or adjoint series, signified by \( ^\ddagger \):

\[
P_t(x) = L_t(x) = L_{-t}(x)^{-1} = \prod_{i=1}^{\infty} (1 + x_i t)^{-1} = \sum_{m=0}^{\infty} \{-1\}^m \{m\} t^m,
\]

\[
Q_t(x) = L_t^\dagger(x) = (L_t(x))^{-1} = \prod_{i=1}^{\infty} (1 + x_i t) = \sum_{m=0}^{\infty} \{1^m\} t^m.
\]

\(^1\text{There are misprints in eqns. (2), (3) of [37] and a weak notation which unfortunately was kept in [10]. To cope notationally with the transformations \( ^* \), \( ^\dagger \), \( ^\ddagger \), one needs to consider the formal parameter \( t \) of the series.}\)
Notice that taking the adjoint is equivalent to the transformation \( t \to -t \), while the inversion \( L \to L^{-1} \) can be viewed as a plethysm.

\[
\begin{align*}
L_t^{-1}(x) &= L_t(-x) = (-1)\circ L_t \\
\tilde{L}_t(x) &= L_{-t}(-x) = (-1)\circ L_{-t}.
\end{align*}
\] (2.13)

The other series\(^2\) and their forms as plethysms are then derived in a similar manner, see [37]. We may be lax about the index \( t \) since we are dealing mainly with the series \( L \) and \( M \). Generally, Schur function series come in pairs which are mutually inverse and consecutively named. One finds

\[
AB = CD = EF = GH = LM = PQ = RS = VW = 1.
\] (2.14)

Generating functions and relations between some of these are displayed in table 2, following [37]. While we are following in this section the habit found in the literature to derive Schur function series from the \( L \) series, the forthcoming sections are based on the \( M \) series to avoid frequent usage of the clumsy notation \( L^{-1} \).

### Table 1: Schur function series: Type, Name=Product, Schur function content, and plethysm

</tr>
</tbody>
</table>

(2.15)

Some remaining series are \( E = LA \), \( F = L^{-1}A^{-1} \), \( G = L^\dagger A \), \( H = \tilde{L}A^{-1} \), \( R = L\tilde{L} \), \( S = L^{-1}L^\dagger \), \( V = AA^{-1} \) and \( W = AA^\dagger \). In the table the following are the characterising properties of the partitions that have been used: \( (\alpha) \) is given in Frobenius notation by,

\[
(\alpha) = \begin{pmatrix}
\alpha_1 \\
\alpha_1 + 1 \\
\alpha_2 + 1 \\
\vdots \\
\alpha_r + 1
\end{pmatrix}
\] (2.16)

and \( \{\gamma\} \) is its conjugate (obtained in Frobenius notation by interchanging the two rows); \( \{\delta\} \) has only even parts and \( \{\beta\} \) is its conjugate; \( \{\epsilon\} \) (not in the table, but related to \( E \)) is self-conjugate; \( \{\zeta\} \) (not in the table, but related to \( F \)) is an arbitrary partition.

We will use \((\ldots)\) as character brackets for the infinitely many new types of characters derived using \( M_{\pi} = \{\pi\} \circ M \) series in the sequel. Often, the index \( \pi \) is replaced by the dimension of the representation \((\ldots)_{\dim} \), but confusion should not occur.

The branching rules for the restriction from \( \text{GL}(n) \) to the subgroups \( \text{GL}(n-1) \), \( \text{O}(n) \) and \( \text{Sp}(n) \) (for \( n \) even) are given by skewing the Schur functions corresponding to characters of \( \text{GL}(n) \) by various infinite

---

\(^2\)The series can be considered to belong to the ring of formal power series \( \Lambda[[t]] \) associated to the ring of symmetric functions \( \Lambda \), which admits a \( \lambda \)-ring structure [30, 20].
Schur function series,

\[
\begin{align*}
\text{GL}(n) & \supset \text{GL}(n-1) & \{\lambda\} \rightarrow \{\lambda/([1]\otimes M)\} = \{\lambda/M\} = ((\lambda/M_1)_{(1)}}, \\
\text{GL}(n) & \supset \text{O}(n) & \{\lambda\} \rightarrow \{\lambda/([2]\otimes M)\} = \{\lambda/D\} = ((\lambda/M_2)_{(2)}, \\
\text{GL}(n) & \supset \text{Sp}(n) & \{\lambda\} \rightarrow \{\lambda/([1^2]\otimes M)\} = \{\lambda/B\} = ((\lambda/M_1^2)_{(1^2)}).
\end{align*}
\]  

(2.17)  

(2.18)  

(2.19)  

The origin of these rules is the fact that \(\text{GL}(n-1), \text{O}(n)\) and \(\text{Sp}(n)\) are the subgroups of \(\text{GL}(n)\) that leave invariant a vector, a symmetric second rank tensor, and an antisymmetric second rank tensor, or in a basis for \(C^n\), objects \(v_i, g_{ij} = g_{ji}, f_{ij} = -f_{ji}\), respectively. It is natural to ask what are the subgroups of \(\text{GL}(n)\) that leave invariant higher rank tensors, such as a third rank fully antisymmetric tensor \(\eta_{ijk} = -\eta_{jik} = -\eta_{ikj}\) would have Young type \(\{1^3\}\). If we denote the corresponding subgroup \(^4\) by \(H_{\pi}(n)\), then the corresponding branching rule is formally given by

\[
\text{GL}(n) \supset H_{\pi}(n) \quad \{\lambda\} \rightarrow \{\lambda/([\pi]\otimes M)\}_\pi = ((\lambda/M_\pi)_{\pi}).
\]  

(2.20)  

More generally, if \(H_\pi(n)\) is the subgroup of \(\text{GL}(n)\) leaving invariant a tensor whose symmetry is specified by the partition \(\pi\), we have\(^5\)

\[
\text{GL}(n) \supset H_\pi(n) \quad \{\lambda\} \rightarrow \{\lambda/([\pi]\otimes M)\}_\pi = ((\lambda/M_\pi)_{\pi}).
\]  

(2.21)  

These formal identities may be inverted through the use of \(L = M^{-1}\) to give

\[
\begin{align*}
\text{GL}(n-1) & \subset \text{GL}(n) & \{\lambda\} \rightarrow \{\lambda/([1]\otimes L)\} = \{\lambda/L\} = \{\lambda/M_{\pi}^{-1}\}, \\
\text{O}(n) & \subset \text{GL}(n) & \{\lambda\} \rightarrow \{\lambda/([2]\otimes L)\} = \{\lambda/C\} = \{\lambda/M_{\pi}^{-1}\}, \\
\text{Sp}(n) & \subset \text{GL}(n) & \{\lambda\} \rightarrow \{\lambda/([1^2]\otimes L)\} = \{\lambda/A\} = \{\lambda/M_{\pi}^{-1}\}, \\
H_{\pi}(n) & \subset \text{GL}(n) & \{\lambda\} \rightarrow \{\lambda/([1^3]\otimes L)\} = \{\lambda/M_{\pi}^{-1}\},
\end{align*}
\]  

(2.22)  

(2.23)  

(2.24)  

(2.25)  

and, more generally, for the subgroup of type \(H_\pi(n)\),

\[
H_\pi(n) \subset \text{GL}(n) \quad \{\lambda\}_\pi \rightarrow \{\lambda/([\pi]\otimes L)\} = \{\lambda/L_\pi\} = \{\lambda/M_{\pi}^{-1}\}.
\]  

(2.26)  

In the following subsections we give some of the systematics of general series \(\Phi\), including \(M_\pi\) and their inverses \(M_\pi^{-1}\) as special cases. These series encode the complexity necessary to deal with the manipulation of formal characters \(\{\lambda\}_\Phi\), including as a special case for the \(M_\pi\) series, the formal characters \(\{\lambda\}_\pi\). Having done this, we will be in a position to examine specific cases of non-classical subgroups \(H_\pi\) as an illustration of the general theme of the paper. In the course of this work, we pause to recall a few notions about the outer Hopf algebra structure of symmetric functions. Switching to a more advanced description will ease the presentation and proofs; appendix B provides the combinatorial details for the more conservative reader.

2.4 “Coproducts” of Schur function series: combinatorics

As will be seen below, a crucial part of the manipulations with branching rules is associated with re-writing a symmetric function of a set of indeterminates \(z = (z_1, z_2, \ldots)\) in terms of symmetric functions of its parts, if it is regarded as partitioned into two subsets \(x = (x_1, x_2, \ldots)\) and \(y = (y_1, y_2, \ldots)\), or in the finite-dimensional case \(z = (x, y) = (x_1, x_2, \ldots, x_m, y_1, y_2, \ldots, y_n)\). For reasons to be explained below, this expansion is here called a ‘coproduct’. For the moment we simply proceed with the explicit steps.

\(^3\)There seem to be only a few instances of research on this or related topics, for example [8].

\(^4\)In principle can consider subgroups which leave invariant a linear combination of tensors of different Young symmetry type, e.g. \(\{1^2\}_1 \equiv \{1^3\} + \{21\}\), but we postpone to investigate this complication until section 4.

\(^5\)Analogously to branching by skewing, formal multiplicative branchings, for example \(\{\lambda\} \rightarrow ((\lambda \cdot M)), \{\lambda\} \rightarrow ((\lambda \cdot D)), \{\lambda\} \rightarrow ((\lambda \cdot B))\), arise in the case of the branching of unitary representations of non-compact Lie groups \([37, 17, 18]\) to representations of a maximal compact Lie subgroup. An analogous generalisation of multiplicative branching, for example \(\{\lambda\} \rightarrow ((\lambda \cdot \{\pi\} \otimes M))\) might equally be considered.
Proposition 2.2: It is well known that
\[
M(x, y) = M(x)M(y), \quad (2.27)
\]
\[
L(x, y) = L(x)L(y), \quad (2.28)
\]
\[
A(x, y) = A(x)A(y) \sum_\sigma (-1)^{|\sigma|} s_\sigma(x) s_\sigma(y), \quad (2.29)
\]
\[
B(x, y) = B(x)B(y) \sum_\sigma s_\sigma(x) s_\sigma(y), \quad (2.30)
\]
\[
C(x, y) = C(x)C(y) \sum_\sigma (-1)^{|\sigma|} s_\sigma(x) s_{\sigma'}(y), \quad (2.31)
\]
\[
D(x, y) = D(x)D(y) \sum_\sigma s_\sigma(x) s_\sigma(y), \quad (2.32)
\]
where $|\sigma| \equiv \omega_\sigma$ is the weight of the partition $\sigma$, and $\sigma'$ denotes the conjugate of $\sigma$. \hfill \Box

Proof: The first of these results (2.27) corresponds to the trivial observation that
\[
M(x, y) = \prod_{i=1}^{m} (1 - x_i)^{-1} \prod_{a=1}^{n} (1 - y_a)^{-1} = M(x)M(y). \quad (2.33)
\]
A similar observation immediately gives (2.28). The derivations of (2.29)-(2.32) depend on the Cauchy identity and its inverse:
\[
C(x, y) = \prod_{\substack{1 \leq i \leq m \\ 1 \leq a \leq n}} (1 - x_i y_a)^{-1} = \sum_\sigma s_\sigma(x) s_\sigma(y), \quad (2.34)
\]
\[
C^{-1}(x, y) = \prod_{\substack{1 \leq i \leq m \\ 1 \leq a \leq n}} (1 - x_i y_a) = \sum_\sigma (-1)^{|\sigma|} s_\sigma(x) s_{\sigma'}(y). \quad (2.35)
\]
These can be used to give, for example,
\[
B(x, y) = \prod_{1 \leq i < j \leq m} (1 - x_i x_j)^{-1} \prod_{1 \leq a \leq n} (1 - x_i y_a)^{-1} \prod_{1 \leq a < b \leq n} (1 - y_a y_b)^{-1}
\]
\[
= B(x) \left( \sum_\sigma s_\sigma(x) s_\sigma(y) \right) B(y), \quad (2.36)
\]
thereby proving (2.30). The remaining results follow in the same way. \hfill \Box

Similarly, using (2.34) more than once in the case of $M_{1^3}(x)$ we find
\[
M_{1^3}(x, y) = M_{1^3}(x) M_{1^3}(y) \sum_{\sigma, \tau} s_\sigma(x) s_{\{1^2\} \otimes \{\tau\}}(x) s_{\{1^2\} \otimes \{\sigma\}}(y) s_\tau(y). \quad (2.37)
\]

More generally we can formulate the important

Proposition 2.3: For any partition $\pi$
\[
M_\pi(x, y) = M_\pi(x) M_\pi(y) \prod_{\xi, \eta < \pi} \prod_{k=1}^{C^\pi_{\xi, \eta}} \sum_{\sigma(\xi, \eta, k)} s_{\xi \otimes \sigma(\xi, \eta, k)}(x) s_{\eta \otimes \sigma(\xi, \eta, k)}(y), \quad (2.38)
\]
where the coefficients $C^\pi_{\xi, \eta}$ are the Littlewood-Richardson coefficients defined by
\[
s_\xi(x) s_\eta(x) = \sum_\pi C^\pi_{\xi, \eta} s_\pi(x), \quad (2.39)
\]
or, equivalently,

\[ s_{\pi}(x, y) = \sum_{\xi, \eta} C_{\xi \eta}^\pi s_\xi(x) s_\eta(y). \]  

(2.40)

**Proof:** Let \( N^\pi = \sum_{\xi \neq \eta} C_{\xi \eta}^\pi \) be the number of summands in the expansion of \( s_{\pi}(x, y) \) in the form (2.40). This includes the two summands \( s_{\pi}(x) \) and \( s_{\pi}(y) \), which may conveniently be taken to be the first and the last, respectively, corresponding to the cases \((\xi, \eta) = (\pi, 0)\) and \((\xi, \eta) = (0, \pi)\), which occur with multiplicity 1. Then

\[ s_{\pi}(x, y) = \sum_{\xi, \eta} C_{\xi \eta}^\pi s_\xi(x) s_\eta(y) = \sum_{k=1}^{N^\pi} s_{\pi(k)}(x) s_{\eta(k)}(y). \]  

(2.41)

It follows that

\[
M_{\pi}(x, y) = \prod_{T \in ST^\pi} \left( 1 - (x, y)^\wgt(T) \right)^{-1} \\
= \prod_{k=1}^{N^\pi} \prod_{U \in ST^{\pi(k)}} \prod_{V \in ST^{\pi(k)}} \left( 1 - \wgt(U) \wgt(V) \right)^{-1} \\
= \prod_{k=1}^{N^\pi} \sum_{\sigma(k)} s_{\sigma(k)}[s_{\xi(k)}](x) s_{\sigma(k)}[s_{\eta(k)}](y) \\
= M_{\pi}(x) M_{\pi}(y) \prod_{k=2}^{N^\pi-1} \sum_{\sigma(k)} s_{\xi(k)} \otimes s_{\eta(k)}(x) s_{\sigma(k)}(y) \\
= M_{\pi}(x) M_{\pi}(y) \prod_{\xi, \eta < \pi} \prod_{k=1}^{N^\pi} \sum_{\sigma(\xi, \eta, k)} s_{\xi} \otimes s_{\eta}(x) s_{\sigma}(y),
\]

(2.42)

where in the second step use has been made of Cauchy’s identity (2.34), while in the third it has been assumed that \( k = 1 \) and \( k = N^\pi \) correspond to the two summands \( s_{\pi}(x) \) and \( s_{\pi}(y) \), respectively. \( \square \)

**Example 2.4:** It follows from Proposition 2.3 that:

\[
M_3(x, y) = M_3(x) M_3(y) \sum_{\sigma, \tau} s_\sigma(x) s_{\{2\} \otimes \tau}(x) s_{\{2\} \otimes \sigma}(y) s_\tau(y),
\]

(2.43)

\[
M_{21}(x, y) = M_{21}(x) M_{21}(y) \sum_{\alpha, \beta, \gamma, \delta} s_\alpha(x) s_\beta(x) s_{\{1\} \otimes \gamma}(x) s_{\{2\} \otimes \delta}(x) \\
\cdot s_{\{1\} \otimes \alpha}(y) s_{\{2\} \otimes \beta}(y) s_\gamma(y) s_\delta(y),
\]

(2.44)

\[
M_{13}(x, y) = M_{13}(x) M_{13}(y) \sum_{\sigma, \tau} s_\sigma(x) s_{\{1\} \otimes \tau}(x) s_{\{1\} \otimes \sigma}(y) s_\tau(y),
\]

(2.45)

\[
M_{11}(x, y) = M_{11}(x) M_{11}(y) \sum_{\rho, \sigma, \tau} s_\rho(x) s_{\{1\} \otimes \sigma}(x) s_{\{1\} \otimes \rho}(y) s_\tau(y) \\
\cdot s_{\{1\} \otimes \rho}(y) s_{\{1\} \otimes \sigma}(y) s_\tau(y).
\]

(2.46)

\[ \square \]

2.5 Series quotients of Schur function products

The previous results allow us to prove the following:
Proposition 2.5: For any partitions $\pi$, $\mu$ and $\nu$

\[
([\mu] [\nu]) / M_{\pi} = \sum_{\sigma(\xi, \eta, k)} \{\mu / (M_{\pi} \prod_{\xi, \eta < \pi} C_{\xi,\eta}^{\pi} \{\xi, \eta, k\})\} \{\nu / (M_{\pi} \prod_{\xi, \eta < \pi} C_{\xi,\eta}^{\pi} \{\xi, \eta, k\})\},
\]

(2.47)

where for each $\xi$, $\eta$ and $k$ the summation is carried out over all partitions $\sigma(\xi, \eta, k)$.

This proposition will be a corollary to our Main Theorem, so we postpone the proof. The reader who feels uneasy with our Hopf algebraic proof might like to compare the proof of proposition 2.5 by combinatorial means in appendix B and is invited to compare with the further development using Hopf algebras. It should be noted in particular that the Lemmas B.19 and B.20 becoming implicit in the structural definitions of the Hopf algebraic machinery rather than requiring separate proofs.

Example 2.6: Proposition 2.5 encompasses by way of example the following results:

\[
([\mu] [\nu]) / M = \{\mu / M\} [\nu / M],
\]

(2.48)

\[
([\mu] [\nu]) / M_2 = \sum_{\sigma} \{\mu / (M_2 \sigma)\} [\nu / (M_2 \sigma)],
\]

(2.49)

\[
([\mu] [\nu]) / M_{12} = \sum_{\sigma} \{\mu / (M_{12} \sigma)\} [\nu / (M_{12} \sigma)],
\]

(2.50)

\[
([\mu] [\nu]) / M_3 = \sum_{\sigma, \tau} \{\mu / (M_3 \sigma (2 \odot \tau))\} [\nu / (M_3 (2 \odot \sigma) \tau)],
\]

(2.51)

\[
([\mu] [\nu]) / M_{21} = \sum_{\alpha, \beta, \gamma, \delta} \{\mu / (M_{21} \alpha \beta (1^2 \odot \gamma) (2 \odot \delta))\}
\]

\[
\cdot [\nu / (M_{21} (1^2 \odot \alpha) (2 \odot \beta) \gamma \delta)],
\]

(2.52)

\[
([\mu] [\nu]) / M_{13} = \sum_{\sigma, \tau} \{\mu / (M_{13} \sigma (1^2 \odot \tau))\} [\nu / (M_{13} (1^2 \odot \sigma) \tau)],
\]

(2.53)

\[
([\mu] [\nu]) / M_{14} = \sum_{\rho, \sigma, \tau} \{\mu / (M_{14} \rho (1^3 \odot \sigma) (1^2 \odot \tau))\}
\]

\[
\cdot [\nu / (M_{14} (1^3 \odot \rho) (1^2 \odot \sigma) \tau)].
\]

(2.54)

2.6 $\pi$-Newell-Littlewood product theorem

Having identified formal characters of representations of subgroups $H_\pi(n)$ of $GL(n)$ in (2.26), we are in a position to combinatorially decompose their tensor products. This may be done by writing such products as products of Schur functions using (2.26), evaluating the Schur function products by means of (2.39) and then restricting the corresponding characters of $GL(n)$ to its subgroup $H_\pi(n)$ by means of (2.21). Our previous Propositions allow us to simplify the results and obtain the general formula given in

Proposition 2.7: Let $([\mu])$ and $([\nu])$ be formal characters of $H_\pi$. Then

\[
([\mu]) ([\nu]) = \sum_{\sigma(\xi, \eta, k)} \{\mu / (M \prod_{\xi, \eta < \pi} C_{\xi,\eta}^{\pi} \{\xi, \eta, k\})\} \{\nu / (M \prod_{\xi, \eta < \pi} C_{\xi,\eta}^{\pi} \{\xi, \eta, k\})\},
\]

(2.55)

where for each $\xi$, $\eta$ and $k$ the summation is carried out over all partitions $\sigma(\xi, \eta, k)$.

The combinatorial proof is given in appendix B. The theorem will be an easy consequence of our Main Theorem in section 4.
Example 2.8: Once again Proposition 2.7 may be illustrated by means of examples:

\[
H_2(n) = \text{GL}(n-1) : \quad \{\mu\} \langle \nu \rangle = \{\mu\} \langle \nu \rangle, \quad (2.56)
\]

\[
H_2(n) = \text{O}(n) : \quad [\mu] [\nu] = \sum_{\sigma} ([\mu/\sigma]([\nu/\sigma]), \quad (2.57)
\]

\[
H_{12}(n) = \text{Sp}(n) : \quad \langle \mu \rangle \langle \nu \rangle = \sum_{\sigma, \tau} ([\mu/\sigma]([\nu/\tau]), \quad (2.58)
\]

\[
H_3(n) : \quad (\langle \mu \rangle \langle \nu \rangle) = \sum_{\sigma, \tau} ((\langle (\mu/\sigma \otimes 2 \otimes \tau) (\nu/\sigma \otimes 2 \otimes \tau) \rangle), \quad (2.59)
\]

\[
H_{21}(n) : \quad (\langle \mu \rangle \langle \nu \rangle) = \sum_{\sigma, \tau} ((\langle (\mu/\sigma \otimes 2 \otimes \tau) (\nu/\sigma \otimes 2 \otimes \tau) \rangle)
\]
\[
\cdot (\nu/(1^2 \otimes \alpha) (2 \otimes \beta) \gamma \delta)), \quad (2.60)
\]

\[
H_{12}(n) : \quad (\langle \mu \rangle \langle \nu \rangle) = \sum_{\sigma, \tau} ((\langle (\mu/\sigma \otimes 2 \otimes \tau) (\nu/\sigma \otimes 2 \otimes \tau) \rangle)
\]
\[
\cdot (\nu/(1^3 \otimes \rho) (1^3 \otimes \tau) \rangle)), \quad (2.61)
\]

\[
H_{12}(n) : \quad (\langle \mu \rangle \langle \nu \rangle) = \sum_{\rho, \sigma, \tau} ((\langle (\mu/\rho \otimes 1^2 \otimes \sigma) (1^3 \otimes \tau) \rangle)
\]
\[
\cdot (\nu/(1^3 \otimes \rho) (1^3 \otimes \sigma) \rangle)), \quad (2.62)
\]

\[\Box\]

3 Nature of the non-classical groups \(H_\pi\)

Before developing the technicalities of our machinery in section 4, we try in the present section to give some hints as to what kinds of groups \(H_\pi\) are to be expected. The subgroups \(H_\pi(n)\) of \(\text{GL}(n)\) leaving invariant a fixed tensor of Young symmetry type \(\pi\) are not necessarily reductive, let alone semi simple Lie groups. The characters \((\langle \lambda \rangle)_{\pi}\) which we study correspond to representations which may be reducible, but not necessarily fully reducible, for \(|\pi| > 2\). The full resolution of these issues is beyond the scope of the present introductory study.

In dealing with concrete examples we have to pass from formal characters to actual characters which implies that there are syzygies, and the representations are not in general free modules. Thus for each \(\pi\) we expect a set of ‘standard’ characters \((\langle \lambda \rangle)_{\pi}\), together with so-called ‘modification rules’ for non-standard ones [14, 36]. As mentioned already, a systematic treatment is beyond the scope of the paper, but some hints can be inferred from working through the examples. At the present level of discussion modification rules must be established on a case-by-case basis, and may even depend for each \(\pi\) on different canonical forms of the invariant tensor of symmetry type \(\pi\). For present purposes we simply regard the \((\langle \lambda \rangle)_{\pi}\) as a list of formal characters associated with the group \(H_\pi\). Here and in the following subsections, we take up the case \(\pi = \{1^3\}\), and discuss some details of branching, product and modification rules for the formal characters \((\langle \lambda \rangle)_{13}\). We drop the index \(\pi = \{1^3\}\) from now on for brevity and notational clarity. In appendix C below further branching and product formulae are given for other cases \{3\}, \{21\} but without any analysis of modification rules.

3.1 \(H_{12}(n)\) in dimension \(n = 3\)

3.1.1 \(\text{SL}(3) \equiv H_{12}(3)\)

Consider the case \(\pi = \{1^3\}\) corresponding to the existence of an invariant totally antisymmetric third rank tensor \(\eta_{ijk}\) satisfying the conditions:

\[
\eta_{ijk} = \eta_{jki} = \eta_{kij} = -\eta_{kji} = -\eta_{jik} = -\eta_{ikj} \quad (3.1)
\]
The requirement that this tensor be invariant under the action of all elements $A \in H_1^3(n)$ gives rise to the constraints

$$A : \eta_{ijk} \rightarrow A_i^p A_j^q A_k^r \eta_{pqr} = \eta_{ijk}$$

(3.2)

with $i, j, k, p, q, r \in \{1, 2, \ldots, n\}$. Here and in what follows Einstein’s convention is followed whereby repeated indices, such as $p$, $q$ and $r$, are summed over their full range of values, in this case $1, 2, \ldots, n$.

In fact for given $n$ there may be more than one canonical form of the invariant tensor $\eta_{ijk}$. For $n = 3$ the canonical form is necessarily defined by $\eta_{ijk} = a\epsilon_{ijk}$ with $\epsilon_{ijk}$ the usual third rank totally antisymmetric tensor in a three-dimensional space such that $\epsilon_{123} = 1$. As can be seen from the constraint conditions (3.2) we can take $a = 1$ without loss of generality and set $\eta_{ijk} = \epsilon_{ijk}$. Using this in (3.2) with $n = 3$ just gives $\eta_{123} = \det A = 1$ and up to isomorphism we can immediately make the identification $H_1^3(3) = \text{SL}(3)$. In this case, therefore, the relevant subgroup of $\text{GL}(3)$ is the semisimple Lie group $\text{SL}(3)$. All its representations are fully reducible and we can identify the characters $((\lambda))$ with Schur functions $s_\lambda(x_1, x_2, x_3)$ with constraint $x_1 x_2 x_3 = 1$ for partitions $\lambda$ of length less than 3. For other cases certain modification rules are required, to which we shall return later. It is immediate that a similar analysis can be carried out for any $\text{SL}(n) = H_1^e(n)$, which gives a unified character theory for all $\text{SL}(n)$ groups.

### 3.1.2 $H_1^3(3)$: Modification rules and $\text{GL}(3) \supset H_1^3(3) = \text{SL}(3)$ branching rules

This special case should be trivial because it corresponds to the well known restriction from $\text{GL}(3)$ to $\text{SL}(3)$. However, even here although the branchings are indeed trivial, the modification rules are somewhat complicated in our formalism.

The branching rule from characters $\{\lambda\}$ of $\text{GL}(3)$ to formal characters $((\mu))$ of $H_1^e(3) = \text{SL}(3)$ takes the form:

$$\text{GL}(3) \supset H_1^3(3) : \quad \{\lambda\} \rightarrow ((\lambda/M_{13}))$$

(3.3)

We use the double parentheses $((\lambda))_\pi$ for the formal characters of $H_\pi$. If the context is clear we drop the index, which may be replaced by the dimension of the representation. Confusion between integer dimension and partitions cannot occur. The particular series employed here reads

$$M_{13} = \{1^3\} \oplus M = \{0\} + \{1^3\} + \{2^3\} + \{3^3\} + \{4^3\} + \cdots ,$$

(3.4)

where it has only been necessary to retain terms of length no greater than 3. This yields the following formal characters, where the subscripts give the dimension of the corresponding representations, or more
precisely the value of the characters and formal characters at the identity.

\[ (3.5) \]

For \(\ell(\mu) \leq 2\), as expected for the branching from \(\text{GL}(3)\) to \(\text{H}_{13}(3) = \text{SL}(3)\), we have \(\{\lambda_1, \lambda_2\} \rightarrow ((\lambda_1, \lambda_2))\). On the other hand for \(\ell(\mu) \geq 3\) we require modification rules to interpret the formal characters of \(\text{H}_{13}(n) = \text{SL}(3)\) in terms of irreducible characters. From the above branchings these must include the following:

\[
\begin{align*}
((111))_0 &= 0 \\
((21))_0 &= 0 \\
((22))_0 &= 0 \\
((311))_0 &= 0 \\
((1111))_{-3} &= -(11) \\
((2111))_{-9} &= -(2) - (11) \\
((2211))_{-8} &= -(21) \\
((2221))_0 &= 0 \\
((3111))_{-18} &= -(3) - (21) \\
\end{align*}
\]

More generally, for any \(((\lambda_1, \lambda_2, \lambda_3, \lambda_4))\) with \(\lambda_1 \geq \lambda_2 \geq \lambda_3 \geq \lambda_4 \geq 0\) the following constitute a complete set of modification rules:

\[
\begin{align*}
((\lambda_1, \lambda_2, \lambda_3, 0)) &= 0 \text{ if } \lambda_3 \geq 1 \\
((\lambda_1, \lambda_1, 1, 1)) &= -((\lambda_1, \lambda_1 - 1)) \text{ if } \lambda_1 = \lambda_2 \geq 1 \\
((\lambda_1, \lambda_2, 1, 1)) &= -((\lambda_1, \lambda_2 - 1)) - ((\lambda_1 - 1, \lambda_2)) \text{ if } \lambda_1 > \lambda_2 \geq 1 \\
((\lambda_1, \lambda_2, 2, 1)) &= 0 \text{ if } \lambda_1 \geq \lambda_2 \geq 2 \\
((\lambda_1, \lambda_2, 2, 2)) &= ((\lambda_1 - 1, \lambda_2 - 1)) \text{ if } \lambda_1 \geq \lambda_2 \geq 2 \\
((\lambda_1, \lambda_2, \lambda_3, \lambda_4)) &= 0 \text{ if } \lambda_3 \geq 3 \\
\end{align*}
\]

(3.7)
3.1.3 Product of characters

As a check we can recover the known $SL(3)$ products through the use of

$$((\mu)) (\nu) = \sum_{\alpha, \beta} ((\mu/\alpha \cdot \{(1^2) \otimes \beta\}) \cdot (\nu/\{(1^2) \otimes \alpha\} \cdot \beta)).$$ (3.8)

For example,

$$((22))_6 ((21))_8 = (((22) \cdot (21))) + (((22/1 \cdot (21/11))) + (((22/22 \cdot (21/2)))$$

$$= ((43)) + ((421)) + ((331)) + ((322)) + ((3211)) + ((2221)) + 2((21)) + 2((22)) + 3((211)) + ((1))$$

$$= ((43))_{24} + (31)_{15} + ((22))_6 + (1)_{3}.$$ (3.9)

where the modification rules have been used in the last step. The result agrees with what we obtain by going up (trivially) from $H_{13}(3) = SL(3)$ to $GL(3)$, carrying out the product in $GL(3)$ and branching to $SL(3)$ by throwing away columns of length greater than 3.

$$((22))_6 ((21))_8 = \{22\} \cdot \{21\} = \{43\} + \{421\} + \{331\} + \{322\}$$

$$= \{43\} + \{31\} + \{22\} + \{1\}$$

$$= ((43))_{24} + ((31))_{15} + ((22))_6 + ((1))_3.$$ (3.10)

3.2 $H_{13}(4)$: branching rules, modification rules, and products of characters.

3.2.1 Matrix realization

Turning to the case $n = 4$ the canonical form of $\eta$ is such that with a suitable scaling

$$\eta_{ijk} = \begin{cases} \epsilon_{abc} & \text{for } (i, j, k) = (a, b, c) \text{ with } a, b, c \in \{1, 2, 3\}; \\ 0 & \text{otherwise.} \end{cases}$$ (3.11)

Thus the constraints (3.2) reduce to

$$A^a_i A^b_j A^c_k \epsilon_{abc} = \eta_{ijk},$$ (3.12)

so that

$$A^p_a A^q_i A^r_k \epsilon_{abc} = \eta_{444} = 0,$$ (3.13)

$$A^p_a A^q_i A^r_k \epsilon_{abc} = \eta_{344} = 0,$$ (3.14)

$$A^p_a A^q_b A^r_i \epsilon_{abc} = \eta_{pq4} = 0,$$ (3.15)

$$A^p_a A^q_b A^r_c \epsilon_{abc} = \eta_{pqr} = \epsilon_{pqr},$$ (3.16)

with $p, q, r \in \{1, 2, 3\}$. The first two constraints (3.13) and (3.14) are satisfied automatically because of the antisymmetry of $\epsilon_{abc}$. The fourth constraint (3.16) gives $\det B = 1$ where $B$ is the $3 \times 3$ submatrix of $A$ such that $B^a_{\alpha} = A^a_{\alpha}$ for all $a, \alpha \in \{1, 2, 3\}$. With this notation (3.16) becomes

$$B^a_p B^b_q B^c_r \epsilon_{abc} = \epsilon_{pqr},$$ (3.17)

so that

$B^{-1} s \epsilon_{pqr} = B^a_p B^b_q B^{-1} s B^c_r \epsilon_{abc} = B^a_p B^b_q \epsilon_{abs}.$ (3.18)

Using this in (3.15) then gives

$$A^a_i B^{-1} s \epsilon_{pqr} = 0.$$ (3.19)
Since this is true for all \( p, q \in \{1, 2, 3\} \) it follows that
\[
A_c^r B_c^{-1} = 0
\] (3.20)
for all \( r \in \{1, 2, 3\} \). Hence
\[
A_c^r B_c^{-1} B_r^d = A_d^d = 0
\] (3.21)
for all \( d \in \{1, 2, 3\} \). Thus \( A \) necessarily takes the form
\[
A = \begin{pmatrix} B & D \\ 0 & C \end{pmatrix} \text{ with } \det B = 1, \det C \neq 0.
\] (3.22)
where \( D \) is an arbitrary \( 3 \times 1 \) matrix, \( C \) is a non-zero \( 1 \times 1 \) matrix and 0 signifies a \( 1 \times 3 \) zero matrix in accordance with (3.21). It follows that \( H_{13}(4) \) is subgroup of \( GL(4) \) consisting of non-singular \( 4 \times 4 \) matrices of the form (3.22). It should be noted that this is an example of an affine group. It is neither semisimple nor reductive, as can be seen from the block triangular form of the defining \( 4 \)-dimensional reducible, but indecomposable, representation (3.22). It contains the reductive group \( SL(3) \times GL(1) \) as a proper subgroup. In fact, we have shown that the formal character theory can be extended to non-semisimple groups in a straightforward manner. The presented example \( H_{13}(4) \) contains after the further branching \( SL(3) \downarrow SO(3) \) the group of motions of a rigid body and has as such potential applications in robotics etc.

3.2.2 Branching rules

First note that the inequivalent finite-dimensional rational irreducible representations of \( GL(4) \) have characters \( \varepsilon^r(\lambda) = \varepsilon^r s_\lambda(x) \) with \( r \) an integer, and \( \lambda = (\lambda_1, \lambda_2, \lambda_3, \lambda_4) \) a partition of length \( \ell(\lambda) \leq 4 \). The parameters \( x = (x_1, x_2, x_3, x_4) \) are the eigenvalues of the group elements \( A \in GL(4) \), and \( \varepsilon \) is the character of the representation \( A \mapsto \det(A) \), so that \( \varepsilon = s_{1^4}(x) = \{1^4\} = x_1x_2x_3x_4 \).

The branching rule from characters \( \{\lambda\} \) of \( GL(4) \) to formal characters \( \{\mu\} \) of \( H_{13}(4) \) takes the form:
\[
GL(4) \supset H_{13}(4) : \quad \{\lambda\} \rightarrow \{(\lambda/M_{1^3})\}
\] (3.23)
with
\[
M_{1^3} = \{1^3\} \bigoplus M = \{0\} + \{1^3\} + \{2^3\} + \{3^3\} + \{4^3\} + \cdots,
\] (3.24)
where it has only been necessary to retain terms of length no greater than 4. This yields the following data, where the subscripts give the dimension of the corresponding representations, or more precisely the value
of the characters and formal characters at the identity.

\[
\begin{array}{|c|c|}
\hline
\{\lambda\}_{\text{dim}} & ((\lambda/M_{1+}))_{\text{dim}} \\
\hline
\{0\}_1 & ((0))_1 \\
\{1\}_4 & ((1))_4 \\
\{11\}_6 & ((11))_6 \\
\{111\}_4 & ((111))_3 + ((0))_1 \\
\{1111\}_1 & ((1111))_{-3} + ((1))_4 \\
\{2\}_10 & ((2))_{10} \\
\{21\}_20 & ((21))_{20} \\
\{211\}_15 & ((211))_{11} + ((1))_4 \\
\{2111\}_4 & ((2111))_{-12} + ((2))_{10} + ((11))_6 \\
\{22\}_20 & ((22))_{20} \\
\{221\}_20 & ((221))_{14} + ((11))_6 \\
\{2211\}_6 & ((2211))_{-17} + ((21))_{20} + ((111))_3 \\
\{222\}_10 & ((222))_6 + ((111))_3 + ((0))_1 \\
\{2221\}_4 & ((2221))_{-8} + ((211))_{11} + ((1111))_{-3} + ((1))_4 \\
\{2222\}_1 & ((2222))_3 + ((2111))_{-12} + ((2))_{10} \\
\{3\}_20 & ((3))_{20} \\
\{31\}_45 & ((31))_{45} \\
\{311\}_36 & ((311))_{26} + ((2))_{10} \\
\{3111\}_10 & ((3111))_{-30} + ((3))_{20} + ((21))_{20} \\
\{32\}_50 & ((32))_{50} \\
\hline
\end{array}
\]

3.2.3 Aspects of $H_{12}(4)$ modification rules

To interpret the formal characters of $H_{12}(4)$ it is necessary to apply modification rules. These are required for all $((\mu))$ with $\mu$ of length $\ell(\mu) = 4$. In these branchings, these formal characters can only arise in cases for which $\lambda$ also has length 4. However, as pointed out above $\{1^4\} = \varepsilon$ is the character of the 1-dimensional determinant representation of $GL(4)$. It follows that

\[
\{\lambda_1, \lambda_2, \lambda_3, \lambda_4\} = \varepsilon^{\lambda_4} \{\lambda_1 - \lambda_4, \lambda_2 - \lambda_4, \lambda_3 - \lambda_4, 0\}.
\]  \hspace{1cm} (3.26)

Applying this to the tabulated identities gives:

\[
\begin{align*}
((1111))_{-3} &= \{1^4\}_1 - ((1))_4 \\
&= \varepsilon((0))_1 - ((1))_4 \\
((2111))_{-12} &= \{2111\}_4 - ((2))_{10} - ((11))_6 \\
&= \varepsilon((1))_4 - ((2))_{10} - ((11))_6 \\
((2211))_{-17} &= \{2211\}_6 - ((21))_{20} - ((111))_3 \\
&= \varepsilon((11))_6 - ((21))_{20} - ((111))_3 \\
((2221))_{-8} &= \{2221\}_4 - ((211))_{11} - ((1111))_{-3} - ((1))_4 \\
&= \varepsilon((111))_4 - ((211))_{11} - \varepsilon((0))_1 + ((1))_4 - ((1))_4 \\
&= \varepsilon((111))_4 + ((0))_1 - ((211))_{11} - \varepsilon((0))_1 \\
&= \varepsilon((111))_4 + ((211))_{11} \\
((2222))_{3} &= \{2222\}_1 - ((2111))_{-12} - ((2))_{10} \\
&= \varepsilon^2((0))_1 - \varepsilon((1))_4 + ((2))_{10} + ((11))_6 - ((2))_{10} \\
&= \varepsilon^2((0))_1 - \varepsilon((1))_4 + ((11))_6 \\
((3111))_{-30} &= \{3111\}_{10} - ((3))_{20} - ((21))_{20} \\
&= \varepsilon((2))_{10} - ((3))_{20} - ((21))_{20} \\
\end{align*}
\]  \hspace{1cm} (3.27)
This gives a collection of modification rules to be applied in the case \( (\mu) \) with \( \ell(\mu) = 4 \). Of course, one would like to have a complete set of modification rules, including those appropriate to \( (\mu) \) with \( \ell(\mu) > 4 \).

### 3.2.4 Product of characters

We can exploit this to analyse products of characters. For example,

\[
((2))_{10}((111))_3 = ((311))_{26} + ((2111))_{-12} + ((2))_{10} + ((11))_6
\]

\[
= ((311))_{26} + \varepsilon((1))_4 - ((2))_{10} - ((11))_6 + ((2))_{10} + ((11))_6
\]

\[
= ((311))_{26} + \varepsilon((1))_4
\]

Further examples of products of \( H_{13}(4) \) characters are given in appendix C.3.

Clearly by proceeding in this way we can build up branching rules, modification rules and product rules for characters for each \( H_{\pi} \) on a case-by-case basis (including for example obtaining each \( SL(n) \) as a subgroup \( H_{13}(n) \) of \( GL(n) \) in a unified framework). However, we now close this heuristic section and pause for an introduction to Hopf algebra methods, so as to start to develop these results into a general theory.

### 4 Hopf algebraic analysis

In section 2.3 the series \( M_{\pi} = \{\pi\} \otimes M \) and associated formal characters for non-classical subgroups were derived from straightforward generalisations of the known combinatorial route to the \( GL(n) \) subgroups \( GL(n-1) \), \( O(n) \) and \( Sp(n) \). The aim of the present section is to embed the combinatorial proofs, given above and in the appendix, into the discussion of branching and product rules, in the context of the Hopf algebraic structure of, and the associated cohomological framework for, symmetric functions as developed in [10]. The Hopf algebraic aspects are well-known in the combinatorial literature [12, 40, 39, 34, 33].

In [10] these branching rules were studied from the point of view of cliffordization (multiplicative deformations) of the algebraic structure, and initial steps were taken towards cohomological classifications. Here and in section 4.1 below we give in outline the basic setting needed to clarify the relationship between series-induced branching rules, and associative deformations (2-cocycles). A detailed development of the Hopf algebra cohomology involved is given in [3]. This algebraic structure is used in a similar manner in [10], and will be utilized in [11]. In section 4.2, standard rules for plethysm distributivity are introduced, transcribed into the language of products and coproducts of symmetric functions. Finally section 4.4 leads into the presentation of a very general class of 2-cochains, of which the present \( \pi \)-branching rules provide examples which are also 2-cocycles. The abstract development is complemented in the appendix A by a brief introduction to a systematic diagrammatical approach using tangles.

The basic structure of interest is the outer Hopf algebra of the ring of symmetric functions \( \Lambda \). Given the canonical Schur scalar product \( \langle \cdot \mid \cdot \rangle : \Lambda \otimes \Lambda \to \mathbb{Z} \) which makes the Schur functions orthonormal,

\[
\langle s_\lambda \mid s_\mu \rangle = \delta_{\lambda\mu},
\]

we define the outer coproduct of any symmetric function \( F \), \( \Delta(F) \), by duality, that is

\[
\langle \Delta(F) \mid G \otimes H \rangle := \langle F \mid G \cdot H \rangle
\]

for any symmetric functions \( G \) and \( H \), where \( \cdot \) is outer multiplication. In the basis of Schur functions this yields using (2.40)

\[
\Delta(s_\pi) = \sum_{\xi,\eta} C^\pi_{\xi\eta} s_\xi \otimes s_\eta.
\]

There is a similar inner coproduct which dualizes inner multiplication of symmetric functions,

\[
\langle \delta(F) \mid G \otimes H \rangle := \langle F \mid G \ast H \rangle
\]
for which the structure constants in the Schur function basis are therefore the structure constants of inner multiplication. In both cases we can adapt the Sweedler convention of affixing bracketed subscripts to denote the list of parts of the coproducts. To distinguish different coproducts we employ the Brouder-Schmitt convention [5] using (1), (2) for the outer coproduct $\Delta$ and [1], [2] for the inner coproduct $\delta$:

$$\Delta(F) = \sum_{\{F\}} F_{(1)} \otimes F_{(2)} = F_{(1)} \otimes F_{(2)}$$

$$\delta(F) = \sum_{[F]} F_{[1]} \otimes F_{[2]} = F_{[1]} \otimes F_{[2]}.$$  \hspace{1cm} (4.5)

For later use we define proper cuts of a coproduct to be the sum of those tensors which do not contain the unit. The proper cut part is denoted by primes,

$$\Delta'(F) = F'_{(1)} \otimes F'_{(2)} = \Delta(F) - F \otimes 1 - 1 \otimes F.$$ \hspace{1cm} (4.6)

The remaining ingredients of the outer Hopf algebra are the antipode antihomomorphism map

$$S(\{\mu\}) = (-1)^{|\mu|}\{\mu'\},$$ \hspace{1cm} (4.7)

where $\mu'$ is the partition conjugate to $\mu$, and the counit character is given by

$$\epsilon(\{\mu\}) = \delta_{\mu0}.$$ \hspace{1cm} (4.8)

The inner product and inner coproduct do not form a Hopf algebra, but only inner convolution algebras. The reader interested in the details may consult [10].

### 4.1 Series-induced branching operators, cliffordization and cohomology

Branchings have a very neat description in terms of Schur function series. One can use Hopf algebra methods to encode this. A linear form $\phi : \Lambda \rightarrow \mathbb{Z}$ acting on the ring of symmetric functions $\Lambda$ with values in $\mathbb{Z}$ is called a 1-cochain. Using such 1-cochains $\phi$, the branching operator obtained by skewing with a series $/\Phi$ reads in Hopf algebraic terms

$$s_{\lambda/\Phi} = \{\lambda\}/\Phi = (\phi \otimes \text{id})\Delta(s_{\lambda})$$ \hspace{1cm} (4.9)

where for given $\Phi$ the 1-cochain $\phi$ is defined by

$$\phi(s_{\mu}) = \langle \Phi \mid s_{\mu} \rangle.$$ \hspace{1cm} (4.10)

The operator $/\Phi$ is called branching operator, recalling the group branchings of (2.17,2.18,2.19). We adopt the convention that 1-cochains are denoted by lower case letters and the corresponding Schur function series by upper case letters. Given a $\text{GL}(n)$ character a branching process using an appropriate branching operator yields Schur functions describing the formal characters of the appropriate $\text{GL}(n)$ subgroup. Under the convolution product one finds an inverse series $\Phi^{-1}$ which allows one to undo the branching. The branching operator $/\Phi$ and its convolutive inverse $/\Phi^{-1}$ can be used to define a new product

$$((A) /\Phi ((B)) = ((A/\Phi^{-1} \cdot B/\Phi^{-1})/\Phi)).$$ \hspace{1cm} (4.11)

It is remarkable, that one can derive a 2-cocycle $(\partial\phi)$ from the linear form $\phi$, which allows one to reinterpret this process as a cliffordization or twist. Using Sweedler indices (see above) we can rewrite the deformed product as

$$A \cdot_{\phi} B = (\partial\phi)(A_{(1)}B_{(1)})A_{(2)}B_{(2)}.$$ \hspace{1cm} (4.12)

The algebra with respect to this product is in general no longer Hopf, but forms a comodule algebra. In general, the branching operator $/\Phi$ is not an algebra homomorphism and the lack of being homomorphic controls the new branchings. In [10] it was investigated in which way Hopf algebra cohomology helps to
classify branching operators. The result was roughly, that one distinguishes 1-cochains which are closed and those that are not closed. The first class yields branching operators \( \Phi \) which are homomorphisms, corresponding to so called group like series \( \Phi \), which are such that

\[
(s_\lambda \cdot s_\mu)/\Phi = s_\lambda/\Phi \cdot s_\mu/\Phi.
\]

This is related to the fact that in these cases

\[
\Delta(\Phi) = \sum_{(\Phi)} \Phi_{(1)} \otimes \Phi_{(2)} = \Phi \otimes \Phi
\]

Group like series are of the general form

\[
\Phi = \prod_{i>0} (1 - f(x_i))^\gamma
\]

where \( f \) is an arbitrary polynomial, and \( \gamma \) is in principle arbitrary (invoking the obvious extension of binomial coefficients in the complex case). The epithet ‘group like’ stems from Hopf algebra theory, where elements with a coproduct \( \Delta(g) = g \otimes g \), just doubling the element, are called group like. The second class of series is more interesting. Such series no longer define homomorphisms but one can introduce a 2-cocycle, derived from the 1-cochain, which describes the deviation from being a homomorphism. In this way Hopf algebra cohomology formalises the classification of these branching rules. Further analysis shows in fact that a cliffordization, that is a Drinfeld twist, underlies this mechanism. Thus as mentioned, the structure of symmetric functions of orthogonal and symplectic type is embedded in deformation theory in the Hopf algebra context. For details we refer to [10].

### 4.2 \( \pi \)-Branchings and products of \( \pi \)-characters.

Having introduced the requisite Hopf algebraic structure for the understanding of branching rules, we now proceed to revisit the combinatorial analysis of proposition 2.3. Firstly we invoke the following properties of plethysms, transcribed into the present setting.

**Lemma 4.9**: For any symmetric functions \( A, B \) and \( C \) we have

\[
A \otimes (B \pm C) = A \otimes B \pm A \otimes C,
\]

right distributivity, \( (4.16) \)

\[
(A + B) \otimes C = \sum A \otimes C_{(1)} \cdot B \otimes C_{(2)}
\]

left binomial expansion \( i \), \( (4.17) \)

\[
(A - B) \otimes C = \sum A \otimes C_{(1)} \cdot B \otimes C_{(2)}
\]

left binomial expansion \( ii \), \( (4.18) \)

\[
A \otimes (B \cdot C) = (A \otimes B) \cdot (A \otimes C),
\]

right homomorphism, \( (4.19) \)

\[
(A \cdot B) \otimes C = \sum A \otimes C_{[1]} \cdot B \otimes C_{[2]},
\]

left hom. expansion, \( (4.20) \)

\[
A \otimes (B \otimes C) = (A \otimes B) \otimes C,
\]

associativity, \( (4.21) \)

These are standard relations given first by Littlewood [24], but see also [25, 27, 26, 30], or more recently, [7, 6] as well as [36], and the web-site of Brian Wybourne.

As pointed out previously, it is sometimes convenient to use an alternative rather suggestive notation for plethysms, by writing \( s_\mu[s_\lambda] = \{\lambda\} \otimes \{\mu\} \equiv \{\lambda\} \otimes^{(\mu)} \). This latter notation will be used in our further development, including that of the following commutativity condition applying to all pairs of partitions \( \lambda \) and \( \mu \):

\[
\Delta(\{\lambda\} \otimes^{(\mu)}) = (\Delta(\{\lambda\})) \otimes^{(\mu)}.
\]

This may be seen by expressing the left hand side of (4.22) in terms of indeterminates \( z = (x, y) \), and then noting that

\[
\Delta(\{\lambda\} \otimes^{(\mu)})(z) = (\{\lambda\} \otimes^{(\mu)})(x, y) = s_\mu[s_\lambda](x, y) = s_\mu[\Delta(\{\lambda\}))(z) = (\Delta(\{\lambda\})) \otimes^{(\mu)},
\]

\[\text{url: } http://www.phys.uni.torun.pl/~bgw/\]
where this is just the right hand side of (4.22).

Alternatively, setting \( x = (x_1, x_2, \ldots, x_m) \) and \( y = (y_1, y_2, \ldots, y_n) \) with \( z = (x, y) \) the above outer coproduct of a plethysm (the left hand side) or plethysm of an outer coproduct (the right hand side) may both be interpreted in terms of branchings from \( \text{GL}(m + n) \) to \( \text{GL}(m) \times \text{GL}(n) \). It is immaterial at what stage the plethysm evaluation is performed. In other words there is an appropriate commuting diagram:

\[
\begin{array}{ccc}
\text{GL}(m + n) & \otimes \{\mu\} & \text{GL}(m + n) \\
\downarrow \Delta & & \downarrow \Delta \\
\text{GL}(m) \otimes \text{GL}(n) & \otimes \{\mu\} & \text{GL}(m) \otimes \text{GL}(n)
\end{array}
\] (4.24)

Or in terms of elements:

\[
\begin{array}{ccc}
\{\lambda\} & \otimes \{\mu\} & \{\lambda\} \otimes \{\mu\} \\
\downarrow \Delta & & \downarrow \Delta \\
\Delta(\{\lambda\}) & \otimes \{\mu\} & \Delta(\{\lambda\} \otimes \{\mu\}) = (\Delta(\{\lambda\})) \otimes \{\mu\}
\end{array}
\] (4.25)

Using this observation we may explicitly evaluate the coproduct of a plethysm as follows:

**Lemma 4.10:** The coproduct of the plethysm \( \{\lambda\} \otimes \{\mu\} \) is given by

\[
\Delta(\{\lambda\} \otimes \{\mu\}) = \sum_{\mu(1)} \cdots \sum_{\mu(N)} \sum_{\lambda} \prod_{k=1}^{N}(\{\lambda(1)_{k}\} \otimes \{\mu(1)_{k}\}) \otimes (\{\lambda(2)_{k}\} \otimes \{\mu(2)_{k}\})
\] (4.26)

where \( N_{\lambda} \) is the number of terms in the outer coproduct of \( \{\lambda\} \). The summations are a variety of Sweedler sums: each \( \sum_{\mu(1)} \) denotes an inner coproduct Sweedler sum, while \( \sum_{(\mu)^N} \) denotes a multiple outer coproduct Sweedler sum.

**Proof:**

\[
\Delta(\{\lambda\} \otimes \{\mu\}) = (\Delta(\{\lambda\})) \otimes \{\mu\} = \left( \sum_{k=1}^{N_{\lambda}} \{\lambda(1)_{k}\} \otimes \{\lambda(2)_{k}\} \right) \otimes \{\mu\}
\]

\[
= \sum_{(\mu)^N} \prod_{k=1}^{N_{\lambda}} \left( \{\lambda(1)_{k}\} \otimes \{\lambda(2)_{k}\} \right) \otimes \{\mu(1)_{k}\}
\]

\[
= \sum_{\mu(1)} \cdots \sum_{\mu(N)} \sum_{\lambda} \prod_{k=1}^{N_{\lambda}} \{\lambda(1)_{k}\} \otimes (\{\lambda(2)_{k}\} \otimes \{\mu(1)_{k}\})
\] (4.27)

Generalizations of the above will be required in which multiple outer coproduct Sweedler sums of the type \( \sum_{(\Phi)^N} \) occur, where \( N \) is the number of Sweedler sums and \( \Phi \) is a Schur function series. In the sequel \( N \) will often be given, as here, by the number \( N_{\lambda} \) of terms in the outer coproduct of some \( \lambda \).

We will need the following corollary for the general formula of the coproduct of the composition of two series. We use 'virtual representations' [20], which are necessary to turn the monoid of representations into an Abelian group à la Grothendieck. The notion \(-\{\mu\} \) is shorthand for \(0 - \{\mu\}\). A proper definition
would include equivalence classes of pairs of representations under the relation \( \{ \mu \} + \{-\{ \mu \} \} = 0 \); this is not displayed here since we need only basic facts about \(-\{ \mu \}\).

**Corollary 4.11:** For any symmetric function \( C \), partition \( \lambda \) and positive integer \( n \), it follows from the lemma 4.9 of plethysms properties

\[
0 \otimes \{ \lambda \} = \delta_{\lambda,(0)} \{ 0 \} \tag{4.28}
\]

\[
0 \otimes C = \langle C \mid \{ 0 \} \rangle \{ 0 \} \tag{4.29}
\]

\[
\{ 0 \} \otimes \{ \lambda \} = \delta_{\ell(\lambda),1} \{ 0 \} = \begin{cases} \{ 0 \} & \text{if } \ell(\lambda) = 1 \text{ that is } \{ \lambda \} = \{ m \} = h(m) \\ 0 & \text{otherwise.} \end{cases} \tag{4.30}
\]

\[
\{ 0 \} \otimes C = \sum_{m \geq 0} \langle C \mid h(m) \rangle \{ 0 \} \tag{4.31}
\]

\[
(n\{ \lambda \}) \otimes C = \{ \{ \lambda \} + \ldots + \{ \lambda \} \} \otimes C \tag{4.32}
\]

\[
(-n\{ \lambda \}) \otimes C = \{ -\{ \lambda \} - \ldots - \{ \lambda \} \} \otimes C \tag{4.33}
\]

where summation over the Sweedler indices is implicitly assumed, and where \( S \) is the antipode of the outer Hopf algebra.

In the next theorem we use both outer and inner coproducts, distinguished by brackets (\( \cdot \)) and [\( [\cdot] \), respectively.

**Theorem 4.12:** (Main Theorem i) For any Schur function series \( \Phi \) and an arbitrary Schur function \( \{ \pi \} \) the outer coproduct of the plethysm \( \{ \pi \} \otimes \Phi \) is given by:

\[
\Delta(\{ \pi \} \otimes \Phi) = \sum_{\{ \pi_1 \}} \cdots \sum_{\{ \pi_n \}} \sum_{(k_1)=1}^{N_1} \ldots \sum_{(k_m)=1}^{N_m} \{ \{ \pi_{(1)k_1} \} \otimes \Phi_{(k_1)[1]} \} \otimes \{ \{ \pi_{(2)k} \} \otimes \Phi_{(k)[2]} \} \tag{4.34}
\]

**Proof:** The result follows immediately from lemma 4.10 by setting \( \lambda = \pi \), replacing \( \mu \) by \( \Phi \) and noting the right distributivity of plethysm with respect to addition (4.16).

Before we draw some conclusions from this theorem, we want to state the even more general result for the coproduct of the plethysm of two Schur function series. Let \( \Xi = \sum_{\lambda} x_{\lambda} s_{\lambda} \), with \( x_{\lambda} \in \mathbb{Z} \), be a Schur function series. Such a series is called Schur positive if all the coefficients \( x_{\lambda} \) are nonnegative. A Schur function series is called (strictly) Schur negative if all coefficients are strictly negative. Obviously any Schur function series can be decomposed into a Schur positive and a Schur negative part \( \Xi = \Xi^+ - \Xi^- = \sum_{\lambda} x_{\lambda}^+ s_{\lambda} - \sum_{\mu} x_{\mu}^- s_{\mu} \), with \( x_{\lambda}^+ \geq 0 \) and \( x_{\mu}^- > 0 \). In the following, we assume that there are finitely many nonzero terms, in order to restrict the iterated coproducts to finite depth. Due to right distributivity of the plethysm the problem can be reduced to the case \( \Xi \otimes \{ \pi \} \).

**Theorem 4.13:** (Main Theorem ii) For any Schur function series \( \Xi = \sum_{\lambda} x_{\lambda}^+ s_{\lambda} - \sum_{\mu} x_{\mu}^- s_{\mu} \) the outer coproduct of \( \Xi \otimes \{ \pi \} \) reads

\[
\Delta(\{ \Xi \} \otimes \{ \pi \}) = \sum_{\{ \pi \}} \prod_{k=1}^{N^+} \prod_{l=1}^{N^-} \{ \lambda_{(1)k} \} \otimes \{ \pi_{(1)(k)[1]} \} \otimes \{ \lambda_{(2)k} \} \otimes \{ \pi_{(2)(k)[2]} \}
\]

\[
\cdot \sum_{\{ \pi \}} \prod_{k=1}^{N^+} \prod_{l=1}^{N^-} \{ \lambda_{(1)k} \} \otimes S(\{ \pi_{(2)(k)[1]} \}) \otimes \{ \lambda_{(2)k} \} \otimes S(\{ \pi_{(2)(k)[2]} \}) \tag{4.35}
\]
where the outer product of the two tensor factors has been left unevaluated for clarity. The composite Sweedler index notation indicates three levels of successive outer coproduct, and a final inner coproduct (see (4.37) below).

**Proof:** Using the right distributivity (4.16) of the plethysm and corollary 4.11, the sum splits into two parts which can be treated by applying lemma 4.10.

\[
\Delta\left(\{\Xi \otimes \{\pi\}\} \otimes \{\pi_2\}\right) = \Delta\left(\{\Xi^+ \otimes \{\pi(1)\}\} \cdot \Delta\left(\{-\Xi^- \otimes \{\pi_2\}\}\right)\right)
\]

Now we consider the first term

\[
\Delta\left(\Xi^+ \otimes \{\pi(1)\}\right) = \Delta\left(\sum_{\lambda = 1}^{N^+} x_\lambda \{\lambda\} \otimes \{\pi(1)\}\right)
\]

\[
= \Delta\left(\prod_{k=1}^{N^+} x_\lambda \{\lambda\} \otimes \{\pi(1)_{(k)}\}\right)
\]

\[
= \sum_{[\sigma]} \prod_{k=1}^{N^+} \prod_{l=1}^{[\sigma]} \left(\{\lambda_{(1)}\} \otimes \{\pi(1)_{(k)}[1]\}\right) \otimes \{\{\lambda_{(2)}\} \otimes \{\pi(1)[2]\}\} \right) \right)
\]

and we can expand the second term in an analogous fashion, where the antipode is given by \(S(\{\pi\}) = (-1)^{|\pi|} \{\pi'\}\). Hence the result follows.

It is clear by now, that the two parts of the Main Theorem allow the computation of the outer coproduct of the plethysm of a polynomial Schur function series and another Schur function series

\[
\Delta(\Xi \otimes \Phi)
\]

The resulting formula is of a remarkable complexity and not displayed. The interested reader should note, that these coproducts are of polynomial type, sometimes called Faà di Bruno coproducts. Such coproducts play a crucial role in renormalization theory and are a typical feature of coproducts emerging from composition. For references see [4].

**4.3 Application to \(M_\pi\)**

While it would be interesting to examine this general case more closely, we want to turn here back to the case of the \(M_\pi\) series treated combinatorially in section 2.3. First we need a few more facts about the \(M\) series itself.

**Lemma 4.14:** The inner coproduct of the \(M\) series is given by the Cauchy kernel (2.34):

\[
\delta M = M_{[1]} \otimes M_{[2]} = \prod_{i,j} \left(1 - x_i y_j\right)^{-1} = \sum_{\sigma} s_{\sigma}(x) s_{\sigma}(y)
\]

The outer coproduct of the \(M\) series is group like:

\[
\Delta M = M_{(1)} \otimes M_{(2)} = \prod_{i} \left(1 - x_i\right)^{-1} \prod_{j} \left(1 - y_j\right)^{-1} = M \otimes M
\]

\[
\Delta^{(k-1)} M = M_{(1)} \otimes \ldots \otimes M_{(k)} = M \otimes \ldots \otimes M
\]
Proof: These are well known identities, stated or partly proved in section 2.4, see (2.34) and (2.33). The final formula can either be seen directly from the product form of \( M \) or deduced recursively. □

**Corollary 4.15:** [Specialization of Main Theorem i), see proposition 2.3]
For any partition \( \pi \), the coproduct of \( M_\pi = \{ \pi \} \otimes M \equiv \{ \pi \} M \) is given by:

\[
\Delta M_\pi = (M_\pi)_{(1)} \otimes M_{(2)} \quad (4.42)
\]

\[
= (M_\pi \otimes M_\pi) \cdot \left( \{ \pi_1' \} \otimes M_{(2)} \right) \quad (4.43)
\]

\[
\quad = \left( M_\pi \otimes M_\pi \right) \cdot \prod_{\xi, \eta, \kappa} \sum_{\kappa = 1}^{C_{\xi, \eta}} \left\{ \{ \xi \} \otimes \{ \sigma(\xi, \eta, \kappa) \} \right\} \otimes \left\{ \{ \eta \} \otimes \{ \sigma(\xi, \eta, \kappa) \} \right\} \quad (4.44)
\]

where the \( C_{\xi, \eta} \) are the Littlewood-Richardson coefficients of outer multiplication. The summations over the \( \sigma(\xi, \eta, \kappa) \) are formally over all Schur functions.

**Proof:** We give an independent proof, since this is the main technical result required to obtain the \( M_\pi \) branchings. First, it should be noted that (4.42) is just Sweedler notation for the decomposition of the coproduct of \( M_\pi \). Its evaluation serves to define the Sweedler sum \( (M_\pi)_{(1)} \otimes M_{(2)} \). Using the suggestive exponential notation, the second form (4.43) comes about by noting that, since \( M_{(k)} = M \) for all \( k \), we have

\[
\Delta M_\pi = \Delta(\{ \pi \} \otimes M) = (\Delta(\{ \pi \})) \otimes M \\
= (\{ \pi \} \otimes \{ 0 \} + \{ 0 \} \otimes \{ \pi \} + \Delta'(\{ \pi \})) \otimes M \\
= (\{ \pi \} \otimes \{ 0 \}) \otimes M \cdot (\{ 0 \} \otimes \{ \pi \}) \otimes M \cdot \Delta'(\{ \pi \})) \otimes M \\
= (\{ \pi \} \otimes \{ 0 \}) \otimes M \cdot (\{ 0 \} \otimes \{ \pi \}) \otimes M \cdot \Delta'(\{ \pi \})) \otimes M \\
\quad = (\{ \pi \} \otimes \{ 0 \}) \otimes M \cdot (\{ 0 \} \otimes \{ \pi \}) \otimes M \\
\quad = (\{ \pi \} \otimes \{ 0 \}) \otimes M \cdot (\{ 0 \} \otimes \{ \pi \}) \otimes M \\
\quad = (\{ \pi \} \otimes \{ 0 \}) \otimes M \cdot (\{ 0 \} \otimes \{ \pi \}) \otimes M = M_\pi \otimes \{ 0 \},
\]

(4.45)

where ‘proper cuts’ (4.6) have been used. The second factor of (4.43) is just \( \Delta'(\{ \pi \}) \otimes M \) expressed in terms of Sweedler sums. To obtain the first factor, it should be noted that as a consequence of (4.19), lemma 4.14 and (4.30), we have

\[
(\{ \pi \} \otimes \{ 0 \}) \otimes M = \{ 0 \} \otimes M_\pi.
\]

Hence

\[
(\{ \pi \} \otimes \{ 0 \}) \otimes M = M_\pi \otimes \{ 0 \} = M_\pi = M_\pi \otimes M_\pi,
\]

(4.47)

as required in (4.45) to give the first factor of (4.43). It only remains to calculate the cut coproduct plethysm. This is given by

\[
\Delta'(\{ \pi \}) \otimes M = \left( \sum_{\sigma} C_{\xi, \eta}^{\pi_1}(\xi) \otimes \{ \eta \} \right) \otimes M = \prod_{\xi, \eta, \kappa} \sum_{\kappa = 1}^{C_{\xi, \eta}} \left\{ \{ \xi \} \otimes \{ \sigma(\xi, \eta, \kappa) \} \right\} \otimes \left\{ \{ \eta \} \otimes \{ \sigma(\xi, \eta, \kappa) \} \right\},
\]

(4.48)

precisely as required. □

Reverting to the Schur function notation for plethysms and introducing indeterminates \( z = (x, y) \) in connection with the coproducts, it is clear that (4.44) coincides with (2.38). Examples of such coproducts have already been displayed in example 2.4.

The skewing by a series amounts to establishing a branching rule from \( \text{GL}(n) \) characters, that is Schur functions, into \( \text{H}_\pi \) characters of a subgroup \( \text{H}_\pi(n) \subset \text{GL}(n) \) which leaves a tensor of symmetry type

\(^7\)In (4.52) below this expression is denoted \( M_{\pi_1} \otimes M_{\pi_2} \) .
\( \pi \) invariant. Such branching rules take the form (2.21), that is \( \{ \lambda \} \to (\lambda/\lambda_{\pi})_{\pi} \). At this point the relation between the structure of the Schur function series and the nature of the branching, mentioned in the introductory remarks to this section, can be discerned. While group like series induce branching operators which are algebra homomorphisms, those series \( M_{\pi} \) with nontrivial plethysms \( |\pi| \geq 2 \), are in general no longer homomorphisms (see section 4.4 and appendix A for further details). The following theorem allows a generalization to arbitrary series \( M_{\pi} \).

**Theorem 4.16:** For any partitions \( \mu, \nu \) and series \( M_{\pi} \) one finds the \( \pi \)-skewed branching formula

\[
(\{\mu\} \cdot \{\nu\})/M_{\pi} = (\mu/\lambda_{\pi}(1)) \cdot (\nu/\lambda_{\pi}(2)) \nonumber
\]

\[
= \sum_{\sigma(\xi,\eta,k)} \mu/(\lambda_{\pi}) \prod_{\xi \eta < \pi} \xi \otimes \sigma(\xi,\eta,k) \cdot \nu/(\lambda_{\pi}) \prod_{\xi \eta < \pi} \eta \otimes \sigma(\xi,\eta,k) \quad (4.49)
\]

where the summations over the \( \sigma(\xi,\eta,k) \) are formally over all Schur functions, and, as usual, \( C_{\xi,\eta}^{\pi} \) indicates the number of terms \( \{\xi\} \otimes \{\eta\} \) appearing in the coproduct of \( \{\pi\} \) for fixed \( \xi \) and \( \eta \).

**Proof:** We make use of the duality mediated by the Schur scalar product

\[
\langle (s_{\mu} \cdot s_{\nu})/M_{\pi} \mid s_{\rho} \rangle = \langle s_{\mu} \otimes s_{\nu} \mid \Delta(M_{\pi} \cdot s_{\rho}) \rangle 
\]

\[
= \langle s_{\mu} \otimes s_{\nu} \mid \Delta(M_{\pi}) \cdot \Delta(s_{\rho}) \rangle 
\]

\[
= \langle s_{\mu} \otimes s_{\nu} \mid (M_{\pi}(1) \otimes (M_{\pi}(2)) \cdot \Delta(s_{\rho}) \rangle 
\]

\[
= \langle s_{\mu}/(M_{\pi}(1) \otimes s_{\rho}/(M_{\pi}(2) \mid \Delta(s_{\rho}) \rangle 
\]

\[
= \langle s_{\mu}/M_{\pi}(1) \cdot s_{\nu}/M_{\pi}(2) \mid s_{\rho} \rangle \quad (4.50)
\]

Since the Schur scalar product is non-degenerate, and since \( s_{\rho} \) was arbitrary and the Schur functions form a basis the result follows, with the final step made by identifying (4.42) with (4.44). This proof does not make use of the property that \( M_{\pi} \) is group like, and thus applies quite generally for all \( \pi \).

Before we can prove the \( \pi \)-generalized version of the Newell-Littlewood theorem we need a Lemma about the coproduct of inverse \( M_{\pi} \) series.

**Lemma 4.17:** Every \( M_{\pi} \) series has as inverse the \( L_{\pi} \) series, furthermore, the part obtained by proper cuts of the coproduct is invertible too

\[
M_{\pi} \cdot L_{\pi} = 1 \nonumber
\]

\[
M_{\pi}(1) \cdot L_{\pi}(1) \otimes M_{\pi}(2) \cdot L_{\pi}(2) = 1 \otimes 1 \quad (4.52)
\]

**Proof:** From the observation that \( M \cdot L = 1 \), we obtain

\[
M_{\pi} \cdot L_{\pi} = (\{\pi\} \otimes M) \cdot (\{\pi\} \otimes L) = \{\pi\} \otimes (M \cdot L) = \{\pi\} \otimes \{0\} = \{0\} = 1 \quad (4.53)
\]

An alternative way to see this reads

\[
M_{\pi} \cdot L_{\pi} = \{\pi\} \otimes M \cdot (-\{\pi\}) \otimes L = \sum_{(M)} \{\pi\} \otimes M(1) \cdot (-\{\pi\}) \otimes M(2)
\]

\[
= (\{\pi\} - \{\pi\}) \otimes M = 0 \otimes M = \delta_{(0),M} = 1 \quad (4.54)
\]

showing that using the identities of the algebra of plethysm, equations (4.17) and (4.29), is much weaker than the first consideration, since we had to make use of the fact that \( M \) is group like. In particular this shows, that the plethysm by a negative Schur function \( -\{\pi\} \) applied to a series \( \Phi \) gives the inverse
\[(\Phi_{\pi})^{-1}\] if and only if \(\Phi\) is group like. The previous result can be used to establish the following identity

\[
1 \otimes 1 = \{0\} \otimes \{0\} = \Delta(\{0\}) = \Delta(M_\pi \cdot L_\pi) = \Delta(M_\pi) \cdot \Delta(L_\pi)
\]

\[
= (M_{\pi(1)} \otimes M_{\pi(2)}) \cdot (L_{\pi(1)} \otimes L_{\pi(2)})
\]

\[
= (M_{\pi(1)} \cdot L_{\pi(1)}) \otimes (M_{\pi(2)} \cdot L_{\pi(2)})
\]

\[
= (M_\pi M_{\pi(1)} L_{\pi(1)} \otimes (M_\pi M_{\pi(2)} L_{\pi(2)})
\]

\[
= (M_\pi L_\pi M_{\pi(1)} L_{\pi(1)} \otimes (M_\pi L_\pi M_{\pi(2)} L_{\pi(2)})
\]

\[
= (M_{\pi(1)} L_{\pi(1)} \otimes (M_{\pi(2)} L_{\pi(2)})
\]

where one should remember that primes at Sweedler indices denote the proper cuts of the coproduct.

\[\Box\]

Products of characters of \(H_\pi(n) \subset GL(n)\) can be obtained using the following generalization of the Newell-Littlewood theorem.

**Theorem 4.18:** [\(\pi\)-Newell-Littlewood theorem, proposition 2.7] Let \((\mu)\) and \((\nu)\) be formal universal characters of \(H_\pi(n)\) defined in terms of Schur functions by \((\mu)\) and \((\nu)\) as in (2.26). Then

\[
((\mu) \cdot (\nu)) = \mu((\pi(1)) \cdot \nu((\pi(2))))
\]

\[
= \sum_{\sigma(\xi,\eta,k)} \left( \prod_{\xi,\eta} \prod_{\xi,\eta} \left( \xi \otimes \sigma(\xi,\eta,k) \right) \cdot \nu(\prod_{\xi,\eta} \prod_{\xi,\eta} \left( \eta \otimes \sigma(\xi,\eta,k) \right)) \right)
\]

where the \(\sigma(\xi,\eta,k)\) that are associated with the Sweedler indices are formally summed over all Schur functions.

**Proof:** We make use of duality, and of the second identity of lemma 4.17 to calculate the product of \(H_\pi(n)\) characters directly in terms of Schur functions:

\[
\langle(\mu) \cdot (\nu) \mid s_\rho\rangle = \langle\mu \otimes \nu \mid L_\pi \otimes L_\pi \cdot \Delta s_\rho\rangle
\]

\[
= \langle\mu \otimes \nu \mid (M_{\pi(1)} L_{\pi(1)} \otimes (M_{\pi(2)} L_{\pi(2)}) L_\pi \otimes L_\pi \cdot \Delta s_\rho\rangle
\]

\[
= \langle\mu \otimes \nu \mid M_{\pi(1)} \otimes M_{\pi(2)} \cdot L_{\pi(1)} \otimes L_{\pi(2)} \cdot L_\pi \otimes L_\pi \cdot \Delta s_\rho\rangle
\]

\[
= \langle\mu M_{\pi(1)} \otimes \nu M_{\pi(2)} \mid \Delta L_\pi \cdot \Delta s_\rho\rangle
\]

\[
= \langle\mu M_{\pi(1)} \otimes \nu M_{\pi(2)} \mid \Delta L_\pi \cdot L_\pi \cdot s_\rho\rangle
\]

\[
= \langle((\mu) \cdot (\nu)) \cdot s_\rho\rangle
\]

The conclusion follows from nondegeneracy of the Schur scalar product, and completeness of the Schur basis.

**Proof:** Alternatively, and more directly, by virtue of the \(GL(n) \supset H_\pi(n)\) branching rule (2.21) and its inverse (2.26), the multiplicity of the \(H_\pi(n)\) character \((\mu)\) in the product \((\mu) \cdot (\nu)\) is given in terms of Schur functions, by:

\[
\langle((\mu) \cdot (\nu)) \mid s_\rho\rangle = \langle\mu L_\pi \cdot \nu L_\pi / M_\pi \mid \Delta L_\pi \cdot s_\rho\rangle
\]

\[
= \langle\mu L_\pi \cdot \nu L_\pi \mid M_\pi \cdot \Delta s_\rho\rangle
\]

\[
= \langle\mu L_\pi \otimes \nu L_\pi \mid \Delta M_\pi \cdot \Delta s_\rho\rangle
\]

\[
= \langle\mu L_\pi \otimes \nu L_\pi \mid \Delta M_\pi \cdot \Delta s_\rho\rangle
\]

\[
= \langle\mu L_\pi \otimes \nu L_\pi \mid M_\pi \otimes M_\pi \cdot ((\pi(1)) \otimes (\pi(2))) \cdot \Delta(\{\rho/L_\pi\})
\]

\[
= \langle\mu L_\pi M_\pi \cdot (\pi(1)) \otimes (\pi(2)) \otimes (\pi(1)) \otimes (\pi(2)) \cdot \Delta(\{\rho/L_\pi\})
\]

\[
= \langle\mu L_\pi M_\pi \cdot (\pi(1)) \otimes (\pi(2)) \otimes (\pi(1)) \otimes (\pi(2)) \cdot \Delta(\{\rho/L_\pi\})
\]

Here (as in the first proof above) use has been made in particular of the proper cut coproduct plethysm (4.43), evaluated by means of (4.44). However note that although the inverse series (equation (4.51)) are
required, the cut product inverse series are not invoked (equation (4.52)). Again the nondegeneracy of the Schur scalar product and the completeness of the Schur basis, allow us immediately to draw the conclusion (4.56), which is in accord with proposition 2.7. This proof is a direct application of definition (4.11) for $\Phi = M_\pi$ and $\Phi^{-1} = L_\pi$.

## 4.4 Scalar products, Cauchy kernels and plethystic generalisations

In the present section we discuss briefly the role of the Cauchy kernel (2.34) and its inverse, the Cauchy-Binet formula and their generalizations in the branching process. In appendix A we give an additional description in terms of tangles which we consider to be helpful in contemplating this structure.

The coproducts of group like branchings induce algebra homomorphisms, which are nontrivial in the sense that they still induce new representations, see the $V$ series in table 2.15, but lie in the trivial cohomology class in the sense of algebra deformation theory.

\[
\Delta \Phi(x, y) = \Phi(x) \Phi(y)
\]

(4.59)

\[
m_\phi(x \otimes y) = (\partial \phi)(x(1), y(1)) x(2) \cdot y(2) = \Phi^{-1}(\Phi(x) \cdot \Phi(y))
\]

(4.60)

The relation between the Schur function series and the linear forms used in branching operators (4.9) is given via the Schur scalar product $\phi = (\Phi | \cdot )$. However, if $O(n)$ or $Sp(n)$ are considered, one is confronted with branchings which are mediated by branching operators which fail to be group like. From the discussion above, we know how the coproduct of series is computed and that the Cauchy kernel plays a key role in the derivation of these results. Moreover, due to plethysms, convolution products of the Cauchy kernel appear, where in one slot or both slots a plethysm takes place.

While the Cauchy kernel (2.34) presents a $0 \rightarrow 2$ map, producing from the 'zero series' 1 a second rank tensor, the Schur scalar product is just a $2 \rightarrow 0$ map which takes a second rank tensor to a number.

\[
1 \rightarrow \prod_{i,j} (1 - x_i y_j)^{-1} = \sum_\sigma u_\sigma \otimes v_\sigma
\]

(4.61)

\[
x \otimes y \rightarrow (x | y)
\]

(4.62)

Note that $u_\sigma, v_\sigma$ is a dual pair of bases with respect to the Schur scalar product. Hence the scalar product and Cauchy kernel are dual objects, this is graphically displayed in equation (A.5). This opens the possibility of studying scalar products which are dual to the coevaluations used in the coproduct formulae of Schur function series. Such a view amounts to introducing a deformation in the product, not in the coproduct. Moreover, this duality explains why the Cauchy kernel

\[
C(x, y) := \prod_{i,j} (1 - x_i y_j)^{-1} = \sum_\sigma u_\sigma \otimes v_\sigma
\]

(4.63)

is a reproducing kernel for Schur function (series) – for, if $F$ is an arbitrary symmetric function, we have

\[
C \cdot F(x) := \sum_\sigma u_\sigma(x) \langle v_\sigma | F \rangle \equiv F(x).
\]

(4.64)

Displayed in the graphical notation this property resembles a Reidemeister move.8

Before we discuss scalar products we consider coproducts with primitive elements, that is power sum symmetric functions. The outer coproduct of a one part power symmetric function $p_n$ has exactly two parts

\[
\Delta (p_n) = p_n \otimes 1 + 1 \otimes p_n
\]

(4.65)

8In fact, the variable $y$ can be considered here to be a linear form on $x$ and the action written $\sum \langle y | C(x, y) F(y) \rangle \. 
For example, for the plethystic deformation using there are homologous 2-cycles, and a major question is to classify all such cycles.

\[ \Delta(\{p_n\} \otimes G) = (p_n \otimes p_0 + p_0 \otimes p_n) \otimes G = (p_n \otimes p_0) \otimes G, \]

where in the last line, only the first Sweedler term in the inner coproduct \( \delta(\{\lambda\}) = \{\lambda\} \otimes \{\lambda\} \) survives. However, due to the inner coproduct this fails for plethysms of the form \( \{p_\lambda\} \otimes G \) for \( \lambda \) a partition having more than one part.

The interesting terms which occur for non group like coproducts induce a twisting exactly such that the lack of being a homomorphism is compensated. This can be seen explicitly in proposition 2.3, where the right hand side has two terms \( M_{\sigma}(x)M_{\tau}(y) \) resembling the part which would be group like, and the twist \( \prod \sum s_{\xi \otimes \sigma}(x)s_{\eta \otimes \sigma}(y) \), related to the proper cuts of \( \Delta(\pi) \). Due to the general theory of such deformations and the fact that we are dealing with group characters, we can conclude that this twisting is a 2-cycle, its dual is also a 2-cocycle. Furthermore, we note that the \( M \) series is the unit of the inner product, and that the Cauchy kernel can be obtained by applying the inner coproduct to the \( M \) series, \( \delta M(x, y) = C(x, y) \). This is the way the Cauchy kernel entered in the branching formulae derived above.

Not all plethysms give rise to different 2-cycles. For example, since the proper cut part of the coproduct of \( \{2\} \) and \( \{1^2\} \) are identical, they induce the same 2-cycle, that is the Cauchy kernel. This shows, that there are homologous 2-cycles, and a major question is to classify all such cycles.

Switching to the dual setting, we consider \( 2 \rightarrow 0 \) maps, which generalize the Schur scalar product. For example, for the plethystic deformation using \( \{1^3\} \), we obtain a new scalar product

\[ (x \mid y)_{\{1^3\}} = \langle x(1) \mid \{1^2\} \otimes y(1) \rangle \langle \{1^2\} \otimes x(2) \mid y(2) \rangle \]

while the Schur scalar product is the special case

\[ (x \mid y) = (x \mid y)_{\{1^2\}} = (x \mid y)_{\{1^2\}} \]

The trivial case \( (x \mid y)_{\{1\}} = \delta_{x,\{0\}} \delta_{y,\{0\}} \) belongs to the group like case. Dualizing the twist for a general \( \pi \) introduced in proposition 2.3 we obtain the family of scalar products

\[ (x \mid y)_\pi = \prod_{\xi,\eta} \langle \{\xi\} \otimes x \mid \{\eta\} \otimes y \rangle \]

which in general is easily seen to be nonisomorphic and noncohomologous to the Schur scalar product. All these scalar products can be used to introduce twists and all of these scalar products induce associative product deformations, since we are dealing with group characters, hence are 2-cocycles.

Our brief discussion shows that the new branchings open also a new research area in deformation theory, since we have a hand on the mechanism to introduce families of appropriate 2-cocycles. A major problem is to classify these 2-cocycles, and to provide tools to be able to decide if two such 2-cocycles are cohomologous. Moreover, the identification of the groups related to these 2-cocycles is important, in relation to the question of whether these families exhaust the space of cohomology classes of 2-cocycles. Some further discussion has been put into appendix A.

5 Conclusions

The present work opens the door into a fascinating new field of group representation techniques. Starting with some Hopf algebraically motivated questions posed in [10] it was possible to derive group branchings tied to the plethystic series of \( M_\pi \) and \( L_\pi \) type. Branchings based on these series led by direct calculations to SL groups considered as subgroups of appropriate GL groups, \( SL(n) \equiv H_{\{1^2\}} \subset GL(n) \). While the general theory works with formal characters in the inductive limit, finite representation spaces require
modification rules to cope with syzygies. This is beyond the scope of the present work, but hints were given in the finite dimensional examples. These examples uncovered non semi simple and non reductive groups, such as affine groups, and more general semi-direct product groups. A case study was presented for \( \text{H}_3(3) \equiv \text{SL}(3) \) and \( \text{H}_3(4) \supset \text{GL}(3) \times \text{GL}(1) \). Character tables, modification rules and products of characters were derived.

We paused the combinatorial exploration to introduce the Hopf algebra machinery which proved to be a powerful way of in encoding the complexity of the new branchings. To our knowledge, these branchings have not appeared in the literature before, since a purely combinatorial route to them would be rather difficult to discern. However, using Hopf algebraic branching operators, we can tie to any Schur function series a branching process. If we restrict ourselves to \( M_\text{c} \) series, these are matrix subgroups of \( \text{GL}(n) \) which fix a tensor of Young symmetry \( T^n \). Particular cases are the branchings \( \text{GL}(n) \downarrow \text{GL}(n-1) \), \( \text{GL}(n) \downarrow \text{O}(n) \) and \( \text{GL}(2n) \downarrow \text{Sp}(2n) \) fixing a vector \( v_i \), a symmetric tensor \( g_{ij} = g_{ji} \), and an antisymmetric tensor \( f_{ij} = -f_{ji} \). The \( \text{SL} \) groups appear through the same mechanism as \( \text{H}_3(n) \subset \text{GL}(n) \) fixing a volume form (antisymmetric highest rank tensor in \( n \) dimension).

The Main Theorem parts i) and ii) (Theorems 4.12 and 4.13) allow in principle the choice of a linear combination of tensors of different Young symmetry type. The formulae obtained have a close relation to vertex operators, which are composed from two Schur function series

\[
\psi_{abcd} - \beta_0 \psi_{abcd}^\perp
\]

representing in part this collaboration. The related invariants are no longer of binary type, and hence necessarily non linear. Such tensors provide ‘interaction terms’ like \( \epsilon_{abcd} \psi^a \psi^b \) in the field equations. There is thus a host of possible applications for our methods, which we hope to explore in future work.

Related to this is the question of whether Hall-Littlewood symmetric functions can be related to the plethystic scalar products, which we defined in section 4.4. Starting from a nontrivial group like branching, one obtains scalar products which have a kernel establishing a residual symmetry in the Schur function series, see \( \psi \sim \psi^\perp \text{H} \). It is known that the freedom of choosing \( q \) to be a root of unity is related to representation theory over finite geometries. This observation should be contrasted with the arbitrary introduction of \( q \)-generalisations via a braided grade group, which has no \textit{a priori} geometrical meaning. The Hopf algebraic treatment may also open a way to understand the modification rules of the involved groups in a systematic way, so that specific case can be examined in the light of more general results.

Finally, the Hopf algebraic treatment does not make explicit use of the ground field. Hence our methods are in principle applicable to \( G \)-sets, working in the Burnside ring, and representations of pro-finite groups on them. This leads to the realm of modular representation theory, and should provide deep insights and beautiful combinatorics.

From a physical point of view, we want to emphasize that groups fixing higher rank tensors are related to non-linear models. For example the antisymmetric tensor \( \epsilon_{abcd} \) in \( n \) dimensions is saturated by \( 4 \) ‘fields’ \( \psi^a \). The related invariants are no longer of binary type, and hence necessarily non linear. Such tensors provide ‘interaction terms’ like \( \epsilon_{abcd} \psi^a \psi^b \) in the field equations. There is thus a host of possible applications for our methods, which we hope to explore in future work.

A Graphical calculus for plethystic (co)scalar products

In this appendix we provide enough notion of graphical calculus [38, 29, 28, 21, 22] to be able to discuss the structure of the 2-cocycles and coscalar products involved in the branching process of the plethystic branchings. The method consist in a graphical representation of the index structure of tensors. A detailed exposition may be found in [9].

Let \( W \) be a (finite dimensional) complex vector space and \( W^* \) its dual. Choose two (nonintersecting) horizontal line, an input line and an output line, where two sets of a nonnegative number of vertices are
positioned. We depict $W$ by a line with downward orientation\(^9\) connecting an upper and lower vertex point, and depict $W^*$ by a similar line with upward orientation.

\[
\begin{align*}
W & \quad W^* & S & \quad T & \quad U \\
\text{id}_W & \quad \text{id}_{W^*} & S^\mu_\nu & \quad T_{\mu_1\ldots\mu_k} & \quad U_{\mu_1\mu_2} \\
\end{align*}
\]

and all summations of these tensors are over the $\nu$ indices (inputs). Operations of maps are represented as dots or boxes in these tangles\(^{10}\). The number of input and output lines of a map may differ, one speaks then of an $k \rightarrow l$ map. Products and coproducts are special such maps of valence $2 \rightarrow 1$ and $1 \rightarrow 2$.

\[
\begin{align*}
\begin{array}{c}
m \\
\end{array} & \quad \Delta
\end{align*}
\]

where we have omitted the orientation. In the case of symmetric functions, the product is the outer product of symmetric functions and the coproduct is the outer coproduct of symmetric functions. The space $W = \oplus V^\otimes n$ is the graded space of symmetric functions in infinitely many variables and $V$ is the grade one space generated by the variables $x_i$.

We use the same graphical notation for series of Schur functions too. Hence we depict the $M$ series or an $A, B, C, D, \ldots, X, \ldots$ series also by a single line. This can be done due to the fundamental theorem of symmetric functions [20], which allows us to regard bases, such as the elementary symmetric functions, complete symmetric functions, Schur functions etc, as new generators of the graded space $W$. The product of two $M$ series is hence given as

\[
m(M(x) \otimes M(y)) \equiv M(x,y)|_{x=y} = M(x, x) = \sum_{n,m} \sum_{\pi} C_{m,n}^\pi \{\pi\}
\]

which is a new series but may not have a standard name like $A, B, C, \ldots$. The same holds true for coproducts. Before we consider such coproducts, we introduce a graphical symbol for the plethysm operation on a Schur function $W[\pi] \equiv \{\pi\} \otimes W$. Furthermore we need the tangles for evaluation, coevaluation, scalar products and coscalar products, i.e. the tangle for the Cauchy kernel $u_i \otimes v_i$ where $u_i$ and $v_i$ are mutually dual bases $\langle u_i | v_j \rangle = \delta_{i,j}$. We depict all this as

\[
\begin{align*}
\begin{array}{c}
\{\pi\} \\
eval
\end{array} & \quad \text{coeval} & \quad \langle , \rangle & \quad u_i \otimes v_i
\end{align*}
\]

Now we start to depict the coproduct for the $M$ series (or any group like series $Y \in \{L, M, V, \ldots\}$) and that of a series $X \in \{A, B, C, D, \ldots\}$.

\[
\begin{align*}
\begin{array}{c}
M_{(1)} & \quad M_{(2)} \\
M & \quad X & \quad R^{(1)} \otimes (1) \cong
\end{array} & \quad X_{(1)} & \quad X_{(2)} & \quad u_i \otimes v_i
\end{align*}
\]

\(^9\)This is the “pessimistic arrow of time”, as coined by Z. Oziewicz in his talk at the ICCA6, 1999 in Ixtapa.

\(^{10}\)One may read these diagrams as a type of flow chart, if the mathematical background of monoidal tensor categories is neglected.
This shows that the deformation for $X$ like series comes up with an $R$-matrix which is built from the Cauchy kernel. Hence the coproduct of $X$ like series can be understood as induced by an $R$-matrix

$$\Delta_X = R^{(1)} \otimes (1) \circ \Delta, \quad \forall X \in \{A, B, C, D, \ldots\}$$  \hspace{1cm} (A.7)

The elements $X$ are all given by plethysms of the form $A = \left\{1^2\right\} \otimes M$, $B = \left\{1^2\right\} \otimes L$, $C = \left\{2\right\} \otimes L$, $D = \left\{2\right\} \otimes M$, in general by a plethysm with $\left\{1^2\right\}$ or $\left\{2\right\}$ of a group like series $Y$. That these two plethysms act in the same way stems from the fact that they possess the same proper cut coproduct

$$\Delta'(2) = \Delta'(1^2) = \left\{1\right\} \otimes \left\{1\right\}$$  \hspace{1cm} (A.8)

The $R$-matrix related to these coproducts is given by the plethysms of a sufficient number of Cauchy kernels (here one) with the proper cut coproduct of the involved Schur function $\pi$. This reads as tangle

$$R^{\Delta'(2)} = R^{\Delta'(1^2)} = R^{(1)} \otimes (1) \cong \left(\begin{array}{c} \begin{array}{c} u_i \otimes v_i \\ u_i \otimes v_i \end{array} \end{array}\right)$$

Since the deformed coproducts are derived from group characters we know, that these coproducts are coassociative. This allows one to conclude that the involved 2-chains are actually 2-cycles. The trivial 2-cycle $\eta \otimes \eta$ yields a trivial deformation $R = 1 \otimes 1$. The next nontrivial case is given by $R^{(1)} \otimes (1) = u_i \otimes v_i$, i.e., induced by the Cauchy kernel itself. The new branchings induced by plethysms of weight greater than 2 are then obtained by applying the proper cut coproduct elements as plethysms to a sufficient number of coevaluations (Cauchy kernels). The resulting formula is that of proposition 2.3, resp. corollary 4.15. If the proper cut coproduct terms of $\pi$ are indexed by $a \ldots xy$, this deformation reads as a tangle

$$\left(\begin{array}{c} \begin{array}{c} \pi_1 a \pi_2 a \pi_1 x \pi_2 x \pi_1 y \pi_2 y \\ \pi_1 a \pi_2 a \pi_1 x \pi_2 x \pi_1 y \pi_2 y \end{array} \end{array}\right) \Leftrightarrow \left(\begin{array}{c} u_i \otimes v_i \\ u_i \otimes v_i \end{array}\right)$$  \hspace{1cm} (A.10)

which might be called “weeping willow” diagram. The framed part of this tangle is again a $0 \rightarrow 2$ tangle, hence a 2-cycle or coscalar product denoted as $u_i^\pi \otimes v_i^\pi$. These 2-cycles are in general homologically different, however, there are degeneracies as $\left(u_i^\pi\right)^{\Delta(2)} = u_i^{(1)} \otimes v_i^{(1)} = \left(u_i^\pi\right)^{\Delta(1^2)}$ clearly shows. Of course, all of the above arguments dualize to yield a theory of 2-cocycles and deformed products. A major question which has to be solved is to classify these scalar products.

**B Combinatorial proofs of propositions 2.5 and 2.7**

To prove in a combinatorial way proposition 2.5 we require, in addition to our previous combinatorial development, hence using no Hopf formalism, a pair of lemmas.

**Lemma B.19**: For any partitions $\lambda$, $\mu$ and $\nu$

$$\left(\{\mu\} \{\nu\}\right) / \lambda = \sum_{\sigma, \tau} C^\lambda_{\mu \tau} \{\mu/\sigma\} \{\nu/\tau\}.$$  \hspace{1cm} (B.1)
**Proof:** In order to prove this we must be more precise about what the left-hand side really means. It can be written more explicitly in the form

\[
\{\mu\} \{\nu\} / \{\lambda\} = (s_\mu(x) s_\nu(x)) / s_\lambda(x) = \sum_\rho C_{\mu\nu}^\rho s_\rho(x),
\]  
(B.2)

Now consider the following two expansions of the same Schur function products:

\[
s_\mu(x, y) s_\nu(x, y) = \sum_\rho C_{\mu\nu}^\rho s_\rho(x, y) = \sum_{\rho, \lambda} C_{\mu\nu}^\rho s_{\lambda/\rho}(x) s_\lambda(y) = \sum_\lambda s_\lambda(y) \left( \sum_\rho C_{\mu\nu}^\rho s_{\lambda/\rho}(x) \right), \tag{B.3}
\]

and

\[
s_\mu(x, y) s_\nu(x, y) = \sum_{\sigma, \tau} s_{\mu/\sigma}(x) s_{\sigma(y)} s_{\nu/\tau}(x) s_{\tau(y)} = \sum_{\sigma, \tau} C_{\sigma\tau}^\lambda s_{\mu/\sigma}(x) s_{\nu/\tau}(x) s_\lambda(y) = \sum_\lambda s_\lambda(y) \left( \sum_{\sigma, \tau} C_{\sigma\tau}^\lambda s_{\mu/\sigma}(x) s_{\nu/\tau}(x) \right). \tag{B.4}
\]

Comparing these two expansions we see that

\[
\sum_\rho C_{\mu\nu}^\rho s_{\lambda/\rho}(x) = \sum_{\sigma, \tau} C_{\sigma\tau}^\lambda s_{\mu/\sigma}(x) s_{\nu/\tau}(x). \tag{B.5}
\]

Thanks to (B.2) this is all that is required to prove Lemma B.19.

Our second lemma is a linear extension of this:

**Lemma B.20:** Let \(Z(x)\) be any series of Schur functions

\[
Z(x) = \sum_\lambda z_\lambda s_\lambda(x), \tag{B.6}
\]

and let the coproduct of \(Z\) take the form

\[
Z(x, y) = \sum_{\sigma, \tau} C_{\sigma\tau}^Z s_\sigma(x) s_\tau(y). \tag{B.7}
\]

Then

\[
\{\mu\} \{\nu\} / Z = \sum_{\sigma, \tau} C_{\sigma\tau}^Z \{\mu/\sigma\} \{\nu/\tau\}. \tag{B.8}
\]

**Proof:** First note that

\[
Z(x, y) = \sum_\lambda z_\lambda s_\lambda(x, y) = \sum_{\lambda, \sigma, \tau} z_\lambda C_{\sigma\tau}^\lambda s_{\sigma}(x) s_\tau(y), \tag{B.9}
\]

so that

\[
C_{\sigma\tau}^Z = \sum_\lambda z_\lambda C_{\sigma\tau}^\lambda. \tag{B.10}
\]
Then, using Lemma B.19

\[
\frac{\{\mu\} \{\nu\}}{Z} = \sum_{\lambda} z_{\lambda} \left( s_{\mu}(x) s_{\nu}(x) \right) / s_{\lambda}(x)
\]

\[
= \sum_{\lambda} z_{\lambda} \sum_{\sigma \tau} C_{\sigma \tau}^{\lambda} \left( s_{\mu/\sigma}(x) s_{\nu/\tau}(x) \right)
\]

\[
= \sum_{\sigma \tau} C_{\sigma \tau}^{Z} \{\mu/\sigma\} \{\nu/\tau\}.
\]  \quad (B.11)

as required.

Proof of proposition 2.5: Returning to proposition 2.5 its proof amounts to replace \( Z \) by \( M_\pi \) in lemma B.20, and substituting into it the \( M_\pi(x, y) \) decomposition from proposition 2.3. This gives

\[
M_\pi(x, y) = \sum_{\sigma \tau} C_{\sigma \tau}^{M_\pi} s_\sigma(x) s_\tau(y)
\]

\[
= M_\pi(x) M_\pi(y) \prod_{0 \neq \xi, \eta \neq \pi} \prod_{k=1}^{C_{\xi \eta}^{\pi}} s_{\xi \otimes \sigma(\xi, \eta, k)}(x) s_{\eta \otimes \sigma(\xi, \sigma, k)}(y).
\]  \quad (B.12)

Using this in (B.8) with \( Z = M_\pi \) then gives (2.47) as required to prove proposition 2.5.

Proof of proposition 2.7: To evaluate the required product of formal characters of \( H_\pi(n) \), one first expresses them in terms of characters of \( GL(n) \) using (2.26), carries out the product in \( GL(n) \) and then expresses the resulting Schur functions back in terms of formal characters of \( H_\pi(n) \) using the branching rule (2.21). This procedure gives

\[
(\{\mu\})(\{\nu\}) = \{\mu/M_\pi^{-1}\} \{\nu/M_\pi^{-1}\} = \left( \left( \{\mu/M_\pi^{-1}\} \{\nu/M_\pi^{-1}\} \right)/M_\pi \right)
\]

\[
= \sum_{\sigma(\xi, \eta, k)} \left( \{\mu/(M_\pi^{-1} M_\pi \prod_{\eta \neq \pi}^{C_{\xi \eta}^{\pi}} \prod_{k=1}^{\xi \otimes \sigma(\xi, \eta, k)} \right) 
\]

\[
\cdot \left( \{\nu/(M_\pi^{-1} M_\pi \prod_{\eta \neq \pi}^{C_{\xi \eta}^{\pi}} \prod_{k=1}^{\eta \otimes \sigma(\xi, \eta, k)} \right) \}
\]

\[
= \sum_{\sigma(\xi, \eta, k)} \left( \{\mu/(\prod_{\eta \neq \pi}^{C_{\xi \eta}^{\pi}} \prod_{k=1}^{\xi \otimes \sigma(\xi, \eta, k)} \} \{\nu/(\prod_{\eta \neq \pi}^{C_{\xi \eta}^{\pi}} \prod_{k=1}^{\eta \otimes \sigma(\xi, \eta, k)} \}ight)
\]  \quad (B.13)

which completes the proof.
C Tables

C.1 \(H_3(4)\) formal characters

Dimensions of \(\text{GL}(4) \downarrow H_3(4)\) irreps:

\hline
\end{array}
\]

From this table one could start to derive modification rules. If we denote a fully symmetric tensor as \(\eta\), then \(((\lambda_1, \lambda_2, \ldots, \lambda_n))\), some \(\lambda_i \geq 3\) can be contracted with \(\eta\). Hence the branching \(\{3\}_20 \downarrow ((3))_{19} + \eta((0))_1\) extracts a triply contracted 'trace' with respect to \(\eta\). However, there is still some freedom, since we find 20 rank three fully symmetric tensors in dimension 4. A more detailed investigation of these affairs is postponed for another publication, since without a theoretical device this task is tied to tedious case by case studies.
